IM1G08D2DDB
1Gbit DDR2 SDRAM
8 BANKS X 16Mbit X 8

Ordering Speed Code	3	25	18
	DDR2-667	DDR2-800	DDR2-1066
Clock Cycle Time (t_{CK3})	5ns	5ns	5ns
Clock Cycle Time (t_{CK4})	3.75ns	3.75ns	3.75ns
Clock Cycle Time (t_{CK5})	3ns	2.5ns	3ns
Clock Cycle Time (t_{CK6})	3ns	2.5ns	2.5ns
Clock Cycle Time (t_{CK7})	-	-	1.875ns
System Frequency ($f_{CK\,max}$)	333MHz	400MHz	533MHz

Features

- High speed data transfer rates with system frequency up to 533 MHz
- 8 internal banks for concurrent operation
- 4-bit Prefetch Architecture
- Programmable $\overline{CAS}$ Latency: 3, 4, 5, 6 and 7
- Programmable Additive Latency: 0, 1, 2, 3, 4, 5 and 6
- Write Latency = Read Latency -1
- Programmable Wrap Sequence: Sequential or Interleave
- Programmable Burst Length: 4 and 8
- Automatic and Controlled Precharge Command
- Power Down Mode
- Auto Refresh and Self Refresh
    Not support self refresh function with Tcase > 95°C
- ODT (On-Die Termination)
- Weak Strength Data-Output Driver Option
- Bi-directional Differential Data Strobe (Single-ended Data Strobe is an optional feature)
- On-Chip DLL aligns DQ and DQS transitions with CK
- $\overline{DQS}$ can be disabled for single-ended data strobe
- Read Data Strobe (RDQS) supported (x8 only)
- Differential clock inputs CK and $\overline{CK}$
- JEDEC Power Supply 1.8V ± 0.1V s
- V_{DDQ} =1.8V ± 0.1V
- Available in 60-ball FBGA for x8 component
- RoHS compliant
- PASR Partial Array Self Refresh
- t_{RAS} Lockout supported
- Average refresh period:
    7.8µs at -40°C ≤ Tcase ≤ +85°C
    3.9µs at 85°C ≤ Tcase ≤ +95°C
    1.95µs at 95°C ≤ Tcase ≤ +105°C
  *Min/Max temperature value depends on the temperature range of the specific device
- Operating temperature range
    - Commercial Tcase = 0°C to +95°C
    - Industrial Tcase = -40°C to +95°C
    - High Temperature Tcase = -40°C to +105°C
  *Tcase must not exceed the maximum operating temperature

    - High -40°C to 105°C Tcase   H

Example Part Number: IM1G08D2DDBG-25I

Description

The IM1G08D2DDB is a eight banks DDR DRAM organized as 8 banks x 16Mbit x 8. The IM1G08D2DDB achieves high speed data transfer rates by employing a chip architecture that prefetches multiple bits and then synchronizes the output data to a system clock.

The chip is designed to comply with the following key DDR2 SDRAM features:(1) posted CAS with additive latency, (2) write latency = read latency-1, (3) On Die Termination.

All of the control, address, circuits are synchronized with the positive edge of an externally supplied clock. I/Os are synchronized with a pair of bidirectional strobes (DQS,$\overline{DQS}$) in a source synchronous fashion.

Operating the four memory banks in an interleaved fashion allows random access operation to occur at a higher rate than is possible with standard DRAMs. A sequential and gapless data rate is possible depending on burst length, $\overline{CAS}$ latency and speed grade of the device.

Part Number Information

IM 1G 08 D2 D D B G - 18 (I)

Intelligent Memory

IC capacity
1G = 1 Gigabits

DRAM I/O width
08 = x8

Memory Type
D2 = DDR2

Voltage
D = 1.8V

IC Revision
D = Revision D

Temperature range
Blank = Commercial Temperature 0℃ to +95℃ Tcase
I = Industrial Temperature -40℃ to +95℃ Tcase
H = High Temperature -40℃ to +105℃ Tcase
Note: The refresh rate must be doubled or 4 times
when the tCase operating temperature exceeds 85℃

Speed Grade
3 = DDR2-667 CL5-5-5
25 = DDR2-800 CL5-5-5
18 = DDR2-1066 CL7-7-7

RoHS-compliance
G = Green / RoHS
Blank = Leaded

Package
B = FBGA

1Gb DDR2 SDRAM Addressing

Signal Pin Description

| Pin	Type	Function
CK, $\overline{CK}$	Input	The system clock input. All inputs except DQs and DMs are sampled on the rising edge of CK.
CKE	Input	Activates the CK signal when high and deactivates the CK signal when low, thereby initiates either the Power Down mode, or the Self Refresh mode.
$\overline{CS}$	Input	$\overline{CS}$ enables the command decoder when low and disables the command decoder when high. When the command decoder is disabled, new commands are ignored but previous operations continue.
$\overline{RAS}$, $\overline{CAS}$, $\overline{WE}$	Input	When sampled at the positive rising edge of the clock, $\overline{RAS}$, $\overline{CAS}$ and $\overline{WE}$ define the command to be executed by the SDRAM.

A0-A13	Input	During a Bank Activate command cycle, A0-A13 defines the row address (RA0-RA13) when sampled at the rising clock edge for x8 device.
		During a Read or Write command cycle, A0-An defines the column address (CA0-CAn) when sampled at the rising clock edge. CAn depends on the SDRAM organization:
		  64Mx8 DDR CAn = CA9
		  32Mx16 DDR CAn = CA9
		
		In addition to the column address, A10(=AP) is used to invoke autoprecharge operation at the end of the burst read or write cycle. If A10 is high, autoprecharge is selected and BA0, BA1 defines the bank to be precharged. If A10 is low, autoprecharge is disabled.
		During a Precharge command cycle, A10(=AP) is used in conjunction with BA0 and BA1 to control which bank(s) to precharge. If A10 is high, all four banks will be precharged simultaneously regardless of state of BA0 and BA1.

BA0 – BA2	Input	Selects which bank is to be active.
DQx	Input/ Output	Data Input/Output pins operate in the same manner as on conventional DRAMs. DQ0-DQ7 for x8 device.
DQS, ($\overline{DQS}$) RDQS, ($\overline{RDQS}$)	Input/ Output	Data Strobe, output with read data, input with write data. Edge-aligned with read data, centered in write data. For x8 device, an RDQS option using DM pin can be enabled via the EMRS(1) to simplify read timing. The data strobes DQS, RDQS may be used in single ended mode or paired with optional complimentary signals $\overline{DQS}$, $\overline{RDQS}$ to provide differential pair signaling to the system during both reads and writes. An EMRS(1) control bit enables or disables all complementary data strobe signals.
DM	Input	DM is an input mask signal for write data. Input data is masked when DM is sampled high along with that input data during a Write access. DM is sampled on both edges of DQS. Although DM pins are input only, the DM loading is designed to match that of DQ and DQS pins. For x8 device, the function of DM or RDQS/ $\overline{RDQS}$ is enabled by EMRS command.
V_{DD}, V_{SS}	Supply	Power and ground for the input buffers and the core logic.
V_{DDQ}, V_{SSQ}	Supply	Isolated power supply and ground for the output buffers to provide improved noise immunity.
V_{REF}	Input	SSTL Reference Voltage for Inputs.
V_{DDL}, V_{SSDL}	Supply	Isolated power supply and ground for the DLL to provide improved noise immunity.
ODT	Input	On Die Termination Enable. It enables termination resistance internal to the DRAM. ODT is applied to each DQ, DQS, $\overline{DQS}$, RDQS, $\overline{RDQS}$ and DM for x8 device. ODT will be ignored if EMRS disable the function.

Simplified State Diagram
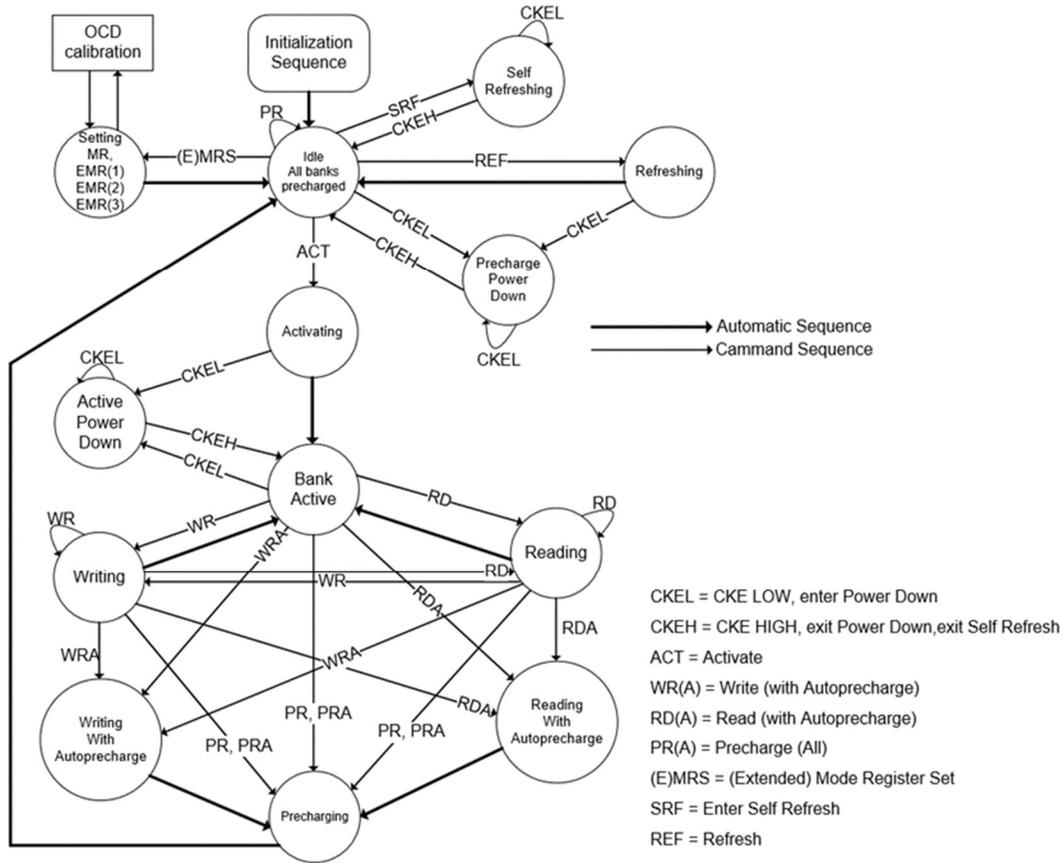

Note: Use caution with this diagram. It is intended to provide a floorplan of the possible state transitions and the commands to control them, not all details. In particular situations involving more than one bank, enabling/disabling on-die termination, Power Down entry/exit – among other things – are not captured in full detail.

Basic Functionality

Read and write accesses to the DDR2 SDRAM are burst oriented; accesses start at a selected location and continue for a burst length of four or eight in a programmed sequence. Accesses begin with the registration of an Active command, which is then followed by a Read or Write command. The address bits registered coincident with the active command are used to select the bank and row to be accessed (BA0, BA1 select the bank; A0-A13 select the row). The address bits registered coincident with the Read or Write command are used to select the starting column location for the burst access and to determine if the autoprecharge command is to be issued.

Prior to normal operation, the DDR2 SDRAM must be initialized. The following sections provide detailed information covering device initialization, register definition, command descriptions and device operation.

Power up and Initialization

DDR2 SDRAMs must be powered up and initialized in a predefined manner. Operational procedures other than those specified may result in undefined operation.

Power-up and Initialization Sequence

The following sequence is required for POWER UP and Initialization.

1. Apply power and attempt to maintain CKE below $0.2*V_{DDQ}$ and ODT[*1] at a low state (all other inputs may be undefined).
    - V_{DD}, V_{DDL} and V_{DDQ} are driven from a single power converter output, AND
    - V_{TT} is limited to 0.95V max, AND
    - V_{REF} tracks $V_{DDQ}/2$.
    or
    - Apply V_{DD} before or at the same time as V_{DDL}.
    - Apply V_{DDL} before or at the same time as V_{DDQ}.
    - Apply V_{DDQ} before or at the same time as V_{TT} & V_{REF}.
    at least one of these two sets of conditions must be met.

2. Start clock and maintain stable condition.

3. For the minimum of 200us after stable power and clock (CK, $\overline{CK}$), then apply NOP or deselect & take CKE high.

4. Wait minimum of 400ns then issue precharge all command. NOP or deselect applied during 400ns period.

5. Issue EMRS(2) command. (To issue EMRS(2) command, provide "Low" to BA0, "High" to BA1)

6. Issue EMRS(3) command. (To issue EMRS(3) command, provide "High" to BA0 and BA1)

7. Issue EMRS to enable DLL. (To issue "DLL Enable" command, provide "Low" to A0, "High" to BA0 and "Low" to BA1 and A12)

8. Issue a Mode Register Set command for "DLL reset". (To issue DLL reset command, provide "High" to A8 and "Low" to BA0-1)

9. Issue precharge all command.

10. Issue 2 or more auto-refresh commands.

11. Issue a mode register set command with low to A8 to initialize device operation. (To program operating parameters without resetting the DLL)

12. At least 200 clocks after step 8, EMRS OCD Default command (A9=A8= A7=1) followed by EMRS OCD Exit command (A9=A8=A7=0) must be issued with other operating parameters of EMRS.

13. The DDR2 SDRAM is now ready for normal operation.

    [*1] To guarantee ODT off, V_{REF} must be valid and a low level must be applied to the ODT pin.

Initialization Sequence after Power Up

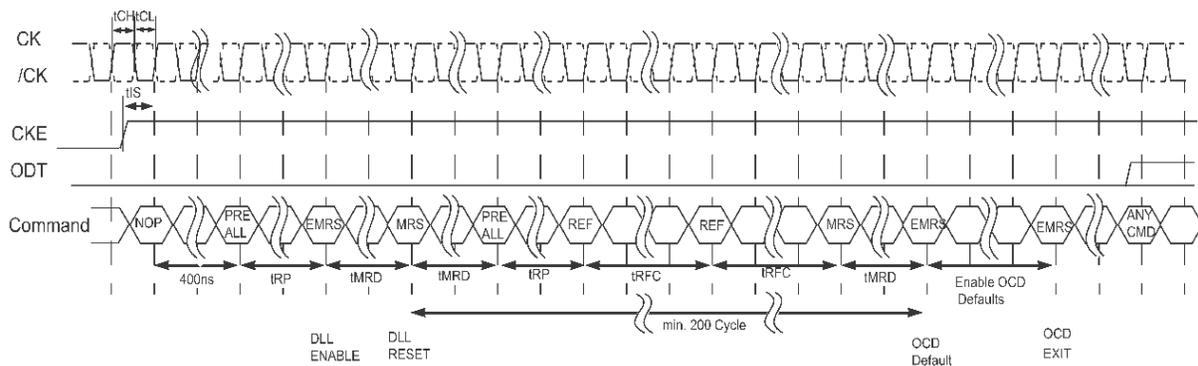

Programming the Mode Register

For application flexibility, burst length, burst type, $\overline{\text{CAS}}$ latency, DLL reset function, write recovery time (t_{WR}) are user defined variables and must be programmed with a Mode Register Set (MRS) command. Additionally, DLL disable function, driver impedance, additive CAS latency, single-ended strobe and ODT (On Die Termination) are also user defined variables and must be programmed with an Extended Mode Register Set (EMRS) command. Contents of the Mode Register (MR) or Extended Mode Registers (EMR(#)) can be altered by re-executing the MRS and EMRS Commands. If the user chooses to modify only a subset of the MRS or EMRS variables, all variables must be redefined when the MRS or EMRS commands are issued.

MRS, EMRS and Reset DLL do not affect array contents, which means reinitialization including those can be executed any time after power-up without affecting array contents.

DDR2 SDRAM Mode Register Set (MRS)

The mode register stores the data for controlling the various operating modes of DDR2 SDRAM. It controls $\overline{CAS}$ latency, burst length, burst sequence, test mode, DLL reset, WR and various vendor specific options to make DDR2 SDRAM useful for various applications. The default value of the mode register is not defined, therefore the mode register must be written after power-up for proper operation. The mode register is written by asserting LOW on $\overline{CS}$, $\overline{RAS}$, $\overline{CAS}$, $\overline{WE}$, BA0 and BA1, while controlling the state of address pins A0 - A13. The DDR2 SDRAM should be in all bank precharge with CKE already HIGH prior to writing into the mode register. The mode register set command cycle time (t_{MRD}) is required to complete the write operation to the mode register. The mode register contents can be changed using the same command and clock cycle requirements during normal operation as long as all banks are in the precharge state. The mode register is divided into various fields depending on functionality. Burst length is defined by A0 - A2 with options of 4 and 8 bit burst lengths. The burst length decodes are compatible with DDR SDRAM. Burst address sequence type is defined by A3, $\overline{CAS}$ latency is defined by A4 - A6. The DDR2 does not support half clock latency mode. A7 is used for test mode. A8 is used for DLL reset. A7 must be set to LOW for normal MRS operation. Write recovery time WR is defined by A9 - A11. Refer to the table for specific codes.

BA1	BA0	MRS mode
0	0	MRS
0	1	EMRS(1)
1	0	EMRS(2): Reserved
1	1	EMRS(3): Reserved

*1 : A13 and BA2 are reserved for future used.

*2 : WR(write recovery for autoprecharge) min is determined by tCK max and WR max is determined by tCK min.
WR in clock cycles is calculated by dividing tWR (in ns) by tCK (in ns) and rounding up a non-integer value to the next integer (WR[cycles] = tWR(ns)/tCK(ns)).
The mode register must be programmed to this value. This is also used with tRP to determine tDAL.

DDR2 SDRAM Extended Mode Register Set

EMRS(1)

The extended mode register(1) stores the data for enabling or disabling the DLL, output driver strength, ODT value selection and additive latency. The default value of the extended mode register is not defined, therefore the extended mode register must be written after power-up for proper operation. Extended mode register(1) is written by asserting low on $\overline{CS}$, $\overline{RAS}$, $\overline{CAS}$, $\overline{WE}$ and high on BA0 and low on BA1, and controlling rest of pins A0 ~ A13.

The DDR2 SDRAM should be in all bank precharge with CKE already high prior to writing into the extended mode register. The mode register set command cycle time (t_{MRD}) must be satisfied to complete the write operation to the extended mode register. Mode register contents can be changed using the same command and clock cycle requirements during normal operation as long as all banks are in the precharge state. A0 is used for DLL enable or disable. A1 is used for enabling reduced strength data-output drive. A3 ~ A5 determines the additive latency. A2 and A6 are used for ODT value selection, A7 ~ A9 are used for OCD control, A10 is used for $\overline{DQS}$ disable and A11 is used for RDQS enable.

DLL Enable / Disable

The DLL must be enabled for normal operation. DLL enable is required during power up initialization, and upon returning to normal operation after having the DLL disabled. The DLL is automatically disabled when entering self-refresh operation and is automatically re-enabled upon exit of self-refresh operation. Any time the DLL is enabled (and subsequently reset), 200 clock cycles must occur before a Read command can be issued to allow time for the internal clock to be synchronized with the external clock. Failing to wait for synchronization to occur may result in a violation of the t_{AC} or t_{DQSCK} parameters.

BA1	BA0	MRS mode
0	0	MRS
0	1	EMRS(1)
1	0	EMRS(2)
1	1	EMRS(3): Reserved

A7	High Temperature Self-Refresh Rate Enable
0	Commercial temperature default
1	Industrial temperature option: use if Tc exceeds 85℃
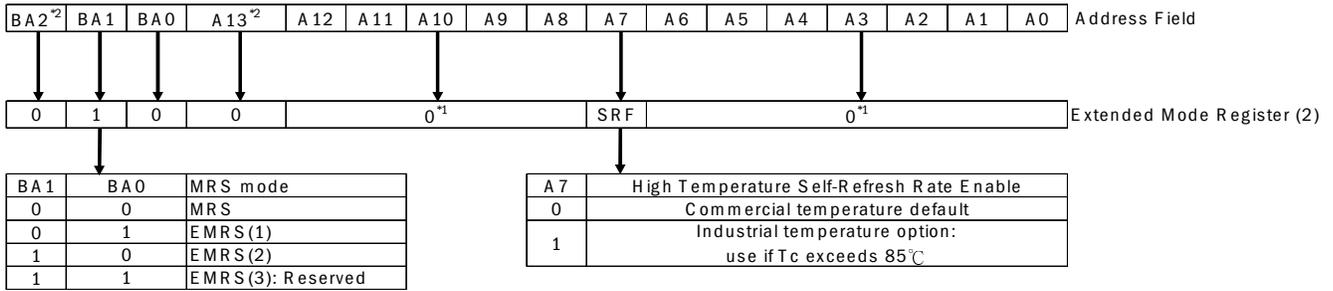

*1 : BA1 must be programmed to 0 setting the mode register during initialization.

*2 : BA2 and A13 are reserved for future usage.

*3 : While 85°C<Tcase<95°C, double refresh rate (tREFI: 3.9us) is required.

While 85°C<Tcase<95°C, 4 times refresh rate (tREFI = 1.95us) is required.

And to enter self refresh mode at this temperature range it must be required an EMRS command to change itself refresh rate.

The PASR bits allows the user to dynamically customize the memory array size to the actual needs. The feature allows the device to reduce standby current by refreshing only the memory arrays that contain essential data. The refresh options are full array, one-half array, one-quarter array, three-fourth array, or none of the array. The mapping of these partitions can start at either the beginning or the end of the address map. Please see the following table.

PASR[2]	PASR[1]	PASR[0]	ACTIVE SECTION
0	0	0	Full array
0	0	1	1/2 array (Banks 0,1,2,3)
0	1	0	1/4 array (Banks 0,1)
0	1	1	1/8 array (Bank 0)
1	0	0	3/4 array (Banks 2,3,4,5,6,7)
1	0	1	1/2 array (Banks 4,5,6,7)
1	1	0	1/4 array (Banks 6,7)
1	1	1	1/8 array (Bank 7)

EMRS(3) Programming: Reserved[*1]

BA2[*2]	BA1	BA0	A13[*2]	A12	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0	Address Field

0	1	0	0							0[*1]							Extended Mode Register (3)
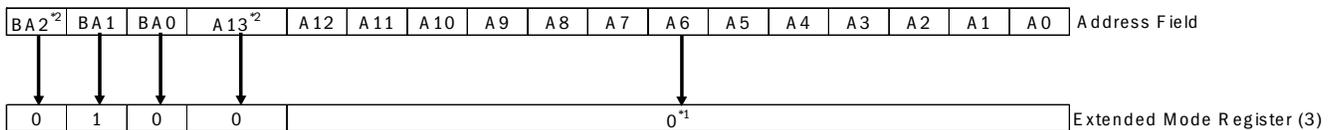

*1 : EMRS(3) is reserved for future use and all bits except BA0 and BA1 must be programmed to 0 when setting the mode register during initialization.

*2 : BA2 and A13 are reserved for future usage.

ODT (on-die termination)

On Die Termination (ODT) is a feature that allows a DRAM to turn on/off termination resistance for each DQ, DQS/$\overline{DQS}$, RDQS/$\overline{RDQS}$ and DM signal for x8 configurations via the ODT control pin. The ODT feature is designed to improve signal integrity of the memory channel by allowing the DRAM controller to independently turn on/off termination resistance for any or all DRAM devices.

The ODT function is supported for ACTIVE and STANDBY modes. ODT is turned off and not supported in SELF REFRESH mode.
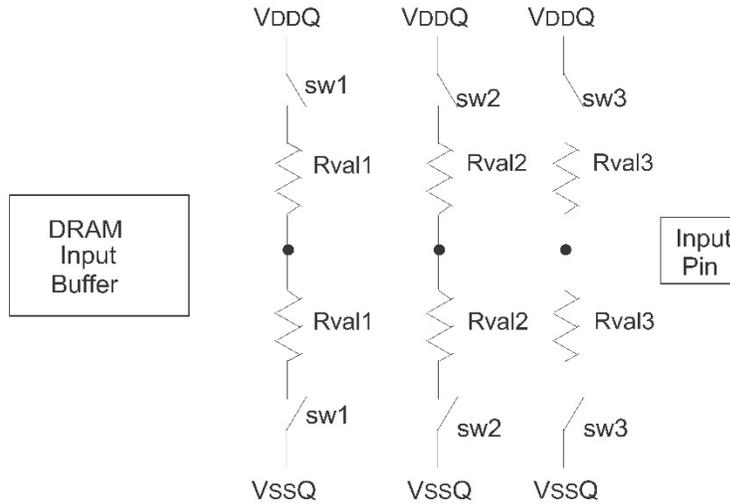

Switch (sw1, sw2, sw3) is enabled by ODT pin.
Selection among sw1, sw2, and sw3 is determined by "Rtt (nominal)" in EMR.
Termination included on all DQs, DM, DQS, $\overline{DQS}$, RDQS, and $\overline{RDQS}$ pins.

Functional representation of ODT

DC Electrical Characteristics and Operation Conditions:

Parameter / Condition	Symbol	MIN	NOM	MAX	Units	Notes
Rtt eff. impedance value for EMRS(A6,A2)= 0,1; 75 ohm	Rtt1(eff)	60	75	90	ohm	1
Rtt eff. impedance value for EMRS(A6,A2)= 1,0; 150 ohm	Rtt2(eff)	120	150	180	ohm	1
Rtt eff. impedance value for EMRS(A6,A2)= 1,1; 50 ohm	Rtt3(eff)	40	50	60	ohm	1,3
Deviation of VM with respect to $V_{DDQ}/2$	Delta VM	-6		+6	%	2

1) Measurement Definition for Rtt(eff):

Apply $V_{IH}(AC)$ and $V_{IL}(AC)$ to test pin seperately, then measure current $I(V_{IH}(AC))$ and $I(V_{IL}(AC))$ respectively

$$Rtt(eff) = (V_{IH}(AC) - V_{IL}(AC)) / (I(V_{IH}(AC)) - I(V_{IL}(AC)))$$

2) Measurement Definition for VM:

Measure voltage (VM) at test pin (midpoint) with no load:

$$Delta\ VM = ((2* VM / V_{DDQ}) - 1) \times 100\%$$

3) Optional for DDR2-667/800/1066

AC Electrical Characteristics and Operation Conditions: For speed 667/800

Symbol	Parameter / Condition	MIN	MAX	Units	Notes
t_{AOND}	ODT turn-on delay	2	2	t_{CK}	
t_{AON}	ODT turn-on	$t_{AC(min)}$	$t_{AC(max)}+0.7$	ns	1
t_{AONPD}	ODT turn-on (Power-Down Mode)	$t_{AC(min)}+2$	$2t_{CK}+t_{AC(max)}+1$	ns	3
t_{AOFD}	ODT turn-off delay	2.5	2.5	t_{CK}	
t_{AOF}	ODT turn-off	$t_{AC(min)}$	$t_{AC(max)}+0.6$	ns	2
t_{AOFPD}	ODT turn-off (Power-Down Mode)	$t_{AC(min)}+2$	$2.5t_{CK}+t_{AC(max)}+1$	ns	3
t_{ANPD}	ODT to Power Down Mode Entry Latency	3	X	t_{CK}	4
t_{AXPD}	ODT Power Down Exit Latency	8		t_{CK}	4

1) ODT turn on time min. is when the device leaves high impedance and ODT resistance begins to turn on.
ODT turn on time max. is when the ODT resistance is fully on. Both are measured from t_{AOND}.

2) ODT turn off time min. is when the device stars to turn-off ODT resistance.
ODT turn off time max. is when the bus is in high impedance. Both are measured from t_{AOFD}.

3) For Standard Active Power-down - with MRS A12 ="0" - the non power-down timings (t_{AOND}, t_{AON}, t_{AOFD} and t_{AOF}) apply.

4) t_{ANPD} and t_{AXPD} define the timing limit when either Power Down Mode Timings (t_{AONPD}, t_{AOFPD}) or Non-Power Down Mode timings (t_{AOND}, t_{AOFD}) have to be applied.

AC Electrical Characteristics and Operation Conditions: For speed 1066

Symbol	Parameter / Condition	MIN	MAX	Units	Notes
t_{AOND}	ODT turn-on delay	2	2	t_{CK}	
t_{AON}	ODT turn-on	$t_{AC(min)}$	$t_{AC(max)}+2.575$	ns	1
t_{AONPD}	ODT turn-on (Power-Down Mode)	$t_{AC(min)}+2$	$3t_{CK}+t_{AC(max)}+1$	ns	3
t_{AOFD}	ODT turn-off delay	2.5	2.5	t_{CK}	
t_{AOF}	ODT turn-off	$t_{AC(min)}$	$t_{AC(max)}+0.6$	ns	2
t_{AOFPD}	ODT turn-off (Power-Down Mode)	$t_{AC(min)}+2$	$2.5t_{CK}+t_{AC(max)}+1$	ns	3
t_{ANPD}	ODT to Power Down Mode Entry Latency	4	X	t_{CK}	4
t_{AXPD}	ODT Power Down Exit Latency	11		t_{CK}	4

1) ODT turn on time min. is when the device leaves high impedance and ODT resistance begins to turn on.
ODT turn on time max. is when the ODT resistance is fully on. Both are measured from t_{AOND}.

2) ODT turn off time min. is when the device stars to turn-off ODT resistance.
ODT turn off time max. is when the bus is in high impedance. Both are measured from t_{AOFD}.

3) For Standard Active Power-down - with MRS A12 ="0" - the non power-down timings (t_{AOND}, t_{AON}, t_{AOFD} and t_{AOF}) apply.

4) t_{ANPD} and t_{AXPD} define the timing limit when either Power Down Mode Timings (t_{AONPD}, t_{AOFPD}) or Non-Power Down Mode timings (t_{AOND}, t_{AOFD}) have to be applied.

ODT Timing for Active / Standby (Idle) Mode and Standard Active Power-Down Mode

1) Both ODT to Power Down Entry and Exit Latency timing parameter tANPD and tAXPD are met, therefore Non-Power Down Mode timings have to be applied.
2) ODT turn-on time ($t_{AON,min}$) is when the device leaves high impedance and ODT resistance begins to turn on. ODT turn on time max. ($t_{AON,max}$) is when the ODT resistance is fully on. Both are measured from t_{AOND}.
3) ODT turn off time min. ($t_{AOF,min}$) is when the device starts to turn off the ODT resistance. ODT turn off time max. ($t_{AOF,max}$) is when the bus is in high impedance. Both are measured from t_{AOFD}.

ODT Timing for Precharge Power-Down and Low Power-Down Mode

1) Both ODT to Power Down Entry and Exit Latencies tANPD and tAXPD are not met, therefore Power-Down Mode timings have to be applied.

Bank Activate Command

The Bank Activate command is issued by holding $\overline{CAS}$ and $\overline{WE}$ high with $\overline{CS}$ and $\overline{RAS}$ low at the rising edge of the clock. The bank addresses of BA0 – BA1 are used to select the desired bank. The row addresses A0 through A13 are used to determine which row to activate in the selected bank for x8 organized components.

The Bank Activate command must be applied before any Read or Write operation can be executed. Immediately after the bank active command, the DDR2 SDRAM can accept a read or write command (with or without Auto-Precharge) on the following clock cycle. If a R/W command is issued to a bank that has not satisfied the $t_{RCD(min)}$ specification, then additive latency must be programmed into the device to delay the R/W command which is internally issued to the device. The additive latency value must be chosen to assure $t_{RCD(min)}$ is satisfied. Additive latencies of 0,1,2,3,4,5 and 6 are supported.

Once a bank has been activated, it must be precharged before another Bank Activate command can be applied to the same bank. The bank active and precharge times are defined as t_{RAS} and t_{RP} respectively.

The minimum time interval between successive Bank Activate commands to the same bank is determined (t_{RC}). The minimum time interval between Bank Active commands, to any other bank, is the Bank A to Bank B delay time (t_{RRD}).

Bank Activate Command Cycle: t_{RCD} = 3, AL = 2, t_{RP} = 3, t_{RRD} = 2

Read and Write Commands and Access Modes

After a bank has been activated, a read or write cycle can be executed. This is accomplished by setting $\overline{RAS}$ high, $\overline{CS}$ and $\overline{CAS}$ low at the clock's rising edge. WE must also be defined at this time to determine whether the access cycle is a read operation ($\overline{WE}$ high) or a write operation ($\overline{WE}$ low). The DDR2 SDRAM provides a wide variety of fast access modes. The boundary of the burst cycle is restricted to specific segments of the page length.

A new burst access must not interrupt the previous 4 bit burst operation in case of BL = 4 setting. Therefore the minimum $\overline{CAS}$ to $\overline{CAS}$ delay (t_{CCD}) is a minimum of 2 clocks for read or write cycles.

For 8 bit burst operation (BL = 8) the minimum $\overline{CAS}$ to $\overline{CAS}$ delay (t_{CCD}) is 4 clocks for read or write cycles. Burst interruption is allowed with 8 bit burst operation. For details see the "Burst Interrupt" - Section of this datasheet.

Read Burst Timing Example: (CL = 3, AL = 0, RL = 3, BL = 4)
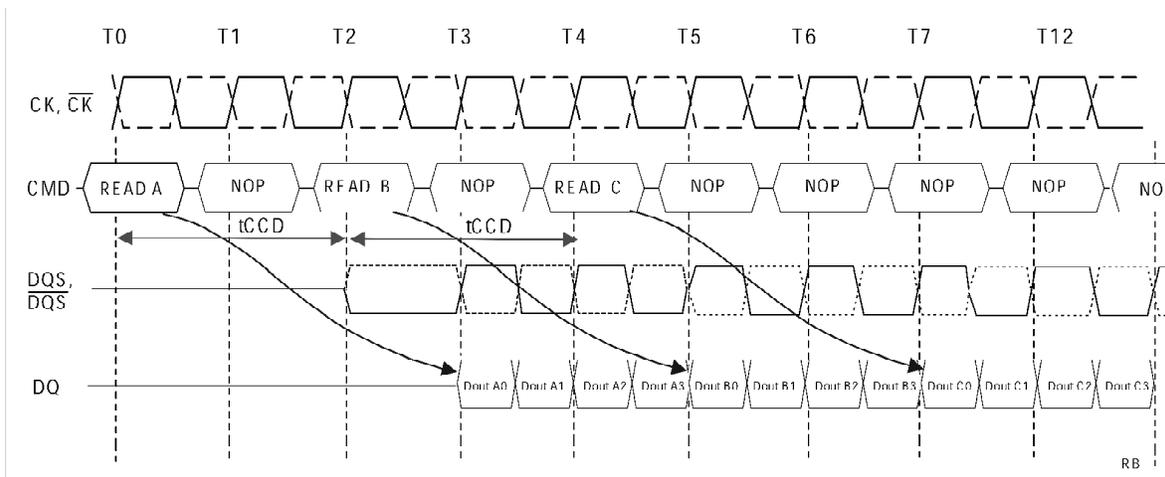

Posted $\overline{CAS}$

Posted $\overline{CAS}$ operation is supported to make command and data bus efficient for sustainable bandwidths in DDR2 SDRAM. In this operation, the DDR2 SDRAM allows a Read or Write command to be issued immediately after the $\overline{RAS}$ bank activate command (or any time during the $\overline{RAS}$ to $\overline{CAS}$ delay time, t_{RCD}, period). The command is held for the time of the Additive Latency (AL) before it is issued inside the device. The Read Latency (RL) is the sum of AL and the $\overline{CAS}$ latency (CL). Therefore if a user chooses to issue a Read/Write command before the $t_{RCD(min)}$, then AL greater than 0 must be written into the EMRS. The Write Latency (WL) is always defined as RL - 1 (Read Latency -1) where Read Latency is defined as the sum of Additive Latency plus $\overline{CAS}$ latency (RL=AL+CL). If a user chooses to issue a Read command after the $t_{RCD(min)}$ period, the Read Latency is also defined as RL = AL + CL.

Read followed by a write to the same bank, Activate to Read delay < $t_{RCD(min)}$:
AL = 2 and CL = 3, RL = (AL + CL) = 5, WL = (RL − 1) = 4, BL = 4
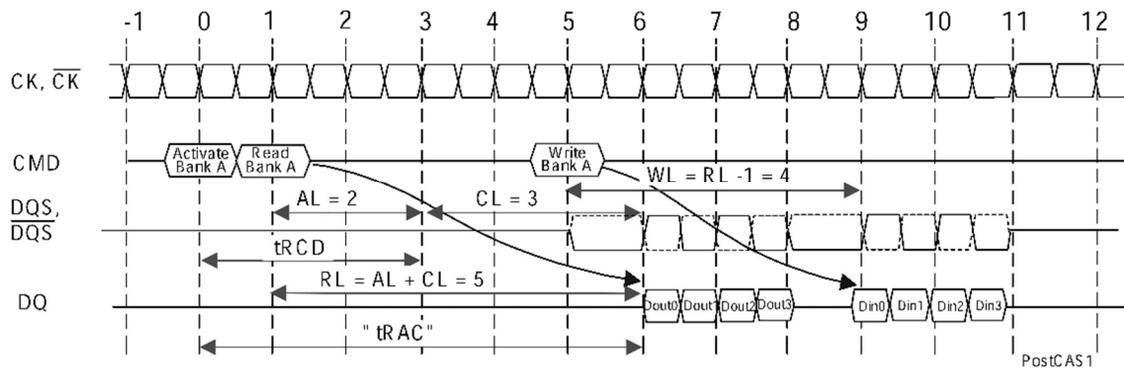

Read followed by a write to the same bank,
where AL = 0 and CL = 3, RL = (AL + CL) = 3, WL =(RL − 1) = 2, BL = 4
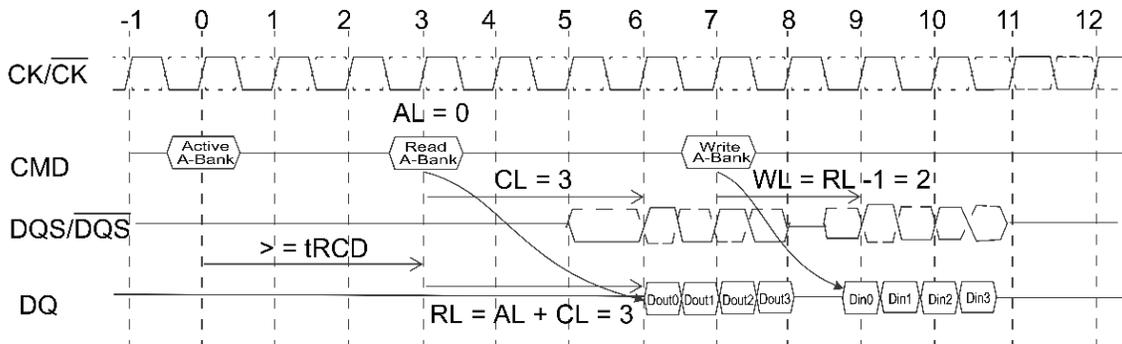

Burst Mode Operation

Burst mode operation is used to provide a constant flow of data to memory locations (write cycle), or from memory locations (read cycle). The parameters that define how the burst mode will operate are burst sequence and burst length. The DDR2 SDRAM supports 4 bit and 8 bit burst modes only. For 8 bit burst-mode, full interleave address ordering is supported, however, sequential address ordering is nibble based for ease of implementation. The burst length is programmable and defined by the addresses A0 ~ A2 of the MRS. The burst type, either sequential or interleaved, is programmable and defined by the address bit 3 (A3) of the MRS. Seamless burst read or write operations are supported. Interruption of a burst read or write operation is prohibited, when burst length = 4 is programmed. For burst interruption of a read or write burst when burst length = 8 is used, see the "Burst Interruption" section of this datasheet. A Burst Stop command is not supported on DDR2 SDRAM devices.

Burst Length and Sequence

Burst Length	Starting Address (A2 A1 A0)	Sequential Addressing (decimal)	Interleave Addressing (decimal)
4	x 0 0	0, 1, 2, 3	0, 1, 2, 3
	x 0 1	1, 2, 3, 0	1, 0, 3, 2
	x 1 0	2, 3, 0, 1	2, 3, 0, 1
	x 1 1	3, 0, 1, 2	3, 2, 1, 0
8	0 0 0	0, 1, 2, 3, 4, 5, 6, 7	0, 1, 2, 3, 4, 5, 6, 7
	0 0 1	1, 2, 3, 0, 5, 6, 7, 4	1, 0, 3, 2, 5, 4, 7, 6
	0 1 0	2, 3, 0, 1, 6, 7, 4, 5	2, 3, 0, 1, 6, 7, 4, 5
	0 1 1	3, 0, 1, 2, 7, 4, 5, 6	3, 2, 1, 0, 7, 6, 5, 4
	1 0 0	4, 5, 6, 7, 0, 1, 2, 3	4, 5, 6, 7, 0, 1, 2, 3
	1 0 1	5, 6, 7, 4, 1, 2, 3, 0	5, 4, 7, 6, 1, 0, 3, 2
	1 1 0	6, 7, 4, 5, 2, 3, 0, 1	6, 7, 4, 5, 2, 3, 0, 1
	1 1 1	7, 4, 5, 6, 3, 0, 1, 2	7, 6, 5, 4, 3, 2, 1, 0

Note: 1) Page length is a function of I/O organization and column addressing.

2) Order of burst access for sequential addressing is "nibble-based" and therefore different from SDR or DDR components.

Burst Read Command

The Burst Read command is initiated by having $\overline{CS}$ and $\overline{CAS}$ low while holding $\overline{RAS}$ and $\overline{WE}$ high at the rising edge of the clock. The address inputs determine the starting column address for the burst. The delay from the start of the command until the data from the first cell appears on the outputs is equal to the value of the read latency (RL). The data strobe output (DQS) is driven low one clock cycle before valid data (DQ) is driven onto the data bus. The first bit of the burst is synchronized with the rising edge of the data strobe (DQS). Each sub-sequent data-out appears on the DQ pin in phase with the DQS signal in a source synchronous manner. The RL is equal to an additive latency (AL) plus $\overline{CAS}$ latency (CL). The CL is defined by the Mode Register Set (MRS). The AL is defined by the Extended Mode Register Set (EMRS).

### Basic Burst Read Timing
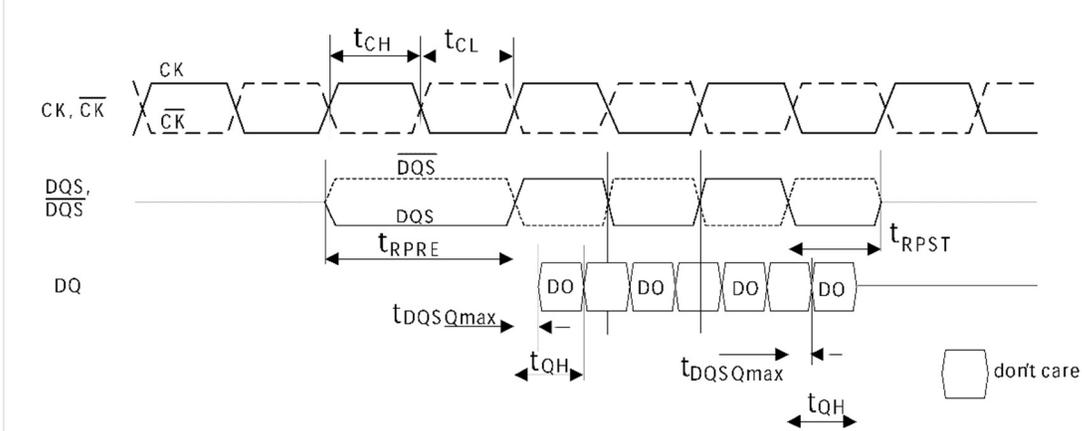

Burst Read Operation: RL = 5 (AL = 2, CL = 3, BL = 4)
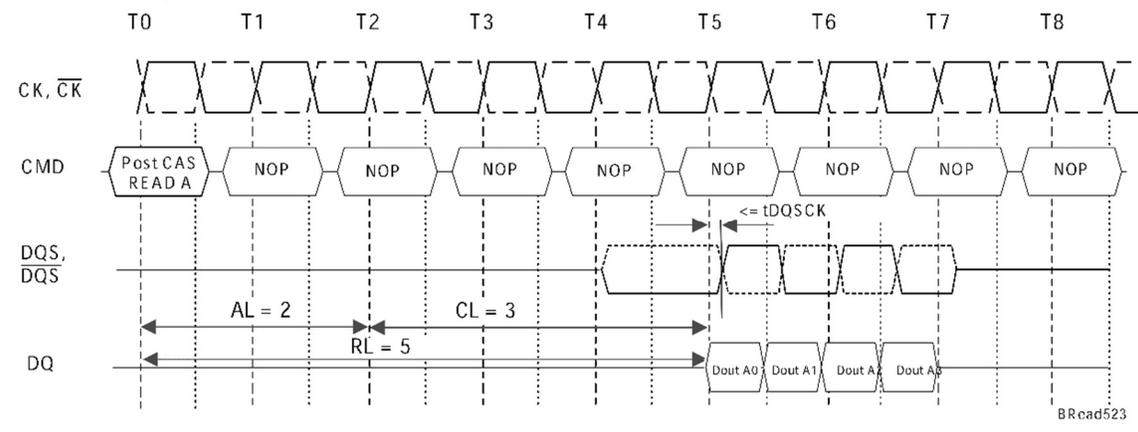

Burst Read Operation: RL = 3 (AL = 0, CL = 3, BL = 8
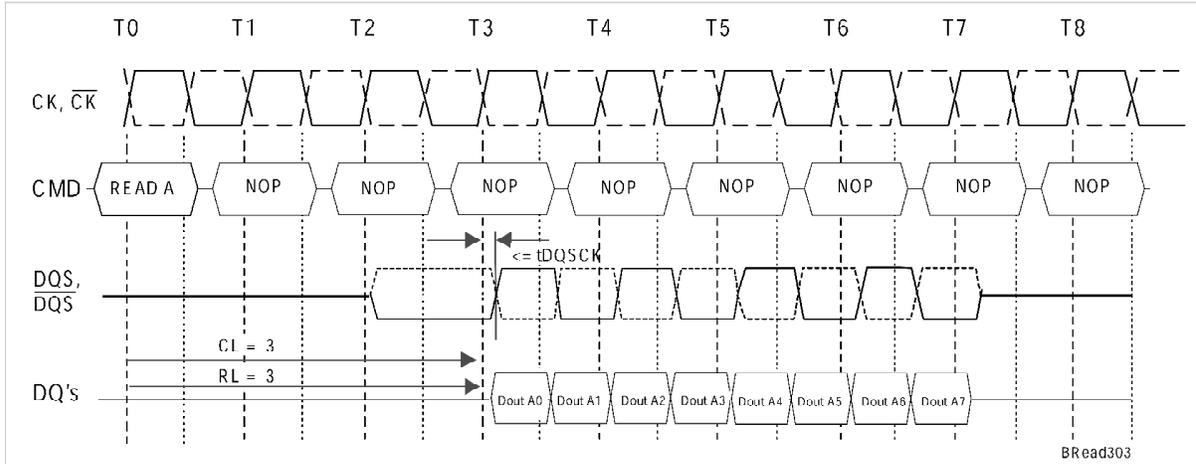

Burst Read followed by Burst Write: RL = 5, WL = (RL – 1) = 4, BL = 4
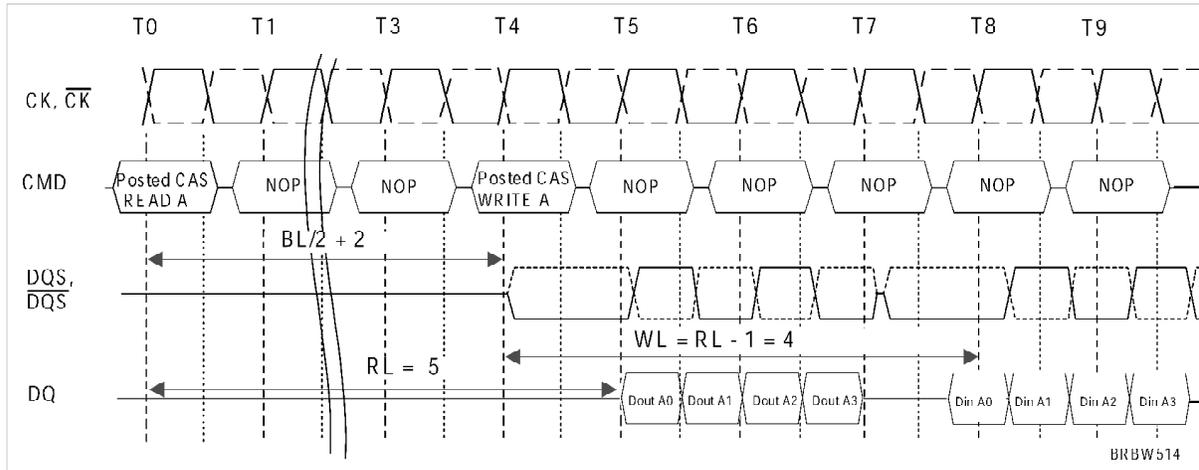

The minimum time from the burst read command to the burst write command is defined by a read-to-write turn-around time, which is BL/2 + 2 clocks.

Seamless Burst Read Option: RL = 5, AL = 2, CL = 3, BL = 4
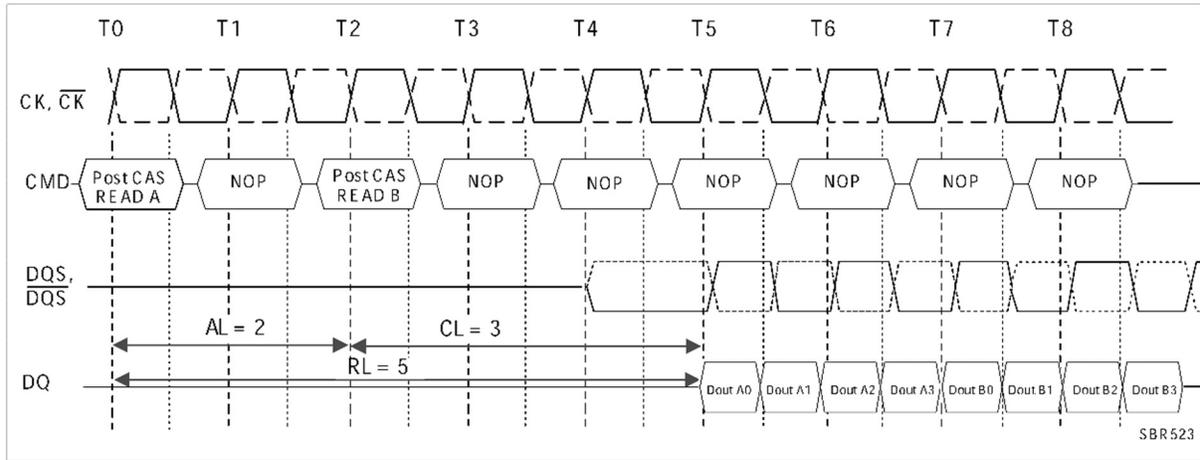

The seamless burst read operation is supported by enabling a read command at every BL / 2 number of clocks. This operation is allowed regardless of same of different banks as long as the banks are activated.

Seamless Burst Read Operation: RL = 3, AL = 0, CL = 3, BL = 8 (non-interrupting)
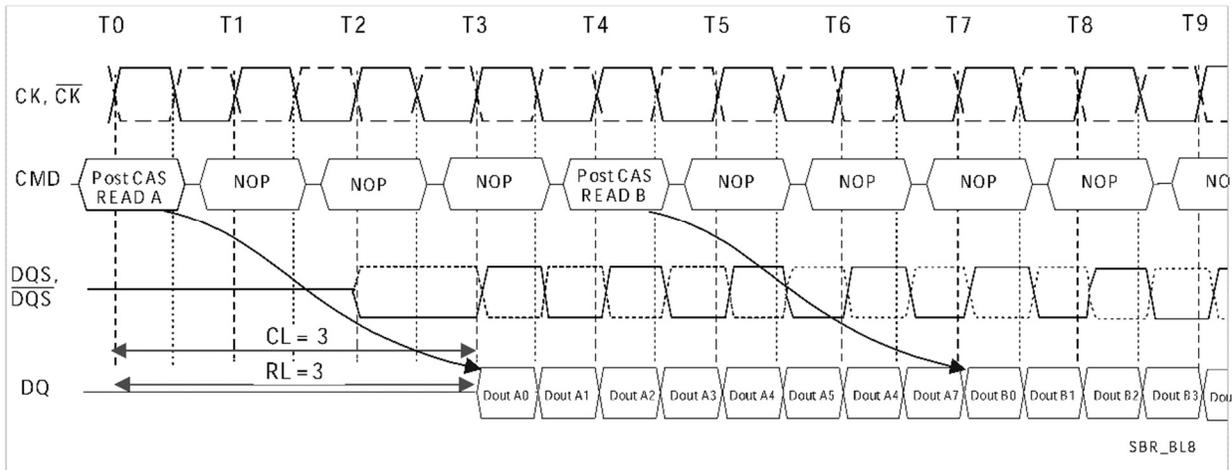

The seamless, non-interrupting 8-bitburst read operation is supported by enabling a read command at every BL / 2 number of clocks. This operation is allowed regardless of same or different banks as long as the banks are activated.

Burst Write Command

The Burst Write command is initiated by having $\overline{CS}$, $\overline{CAS}$ and $\overline{WE}$ low while holding $\overline{RAS}$ high at the rising edge of the clock. The address inputs determine the starting column address. Write latency (WL) is defined by a read latency (RL) minus one and is equal to (AL + CL -1). A data strobe signal (DQS) should be driven low (preamble) one clock prior to the WL. The first data bit of the burst cycle must be applied to the DQ pins at the first rising edge of the DQS following the preamble. The t_{DQSS} specification must be satisfied for write cycles. The subsequent burst bit data are issued on successive edges of the DQS until the burst length is completed. When the burst has finished, any additional data supplied to the DQ pins will be ignored. The DQ signal is ignored after the burst write operation is complete. The time from the completion of the burst write to bank precharge is named "write recovery time" (t_{WR}) and is the time needed to store the write data into the memory array. t_{WR} is an analog timing parameter (see the AC table in this specification) and is not the programmed value for WR in the MRS.

Basic Burst Write Timing
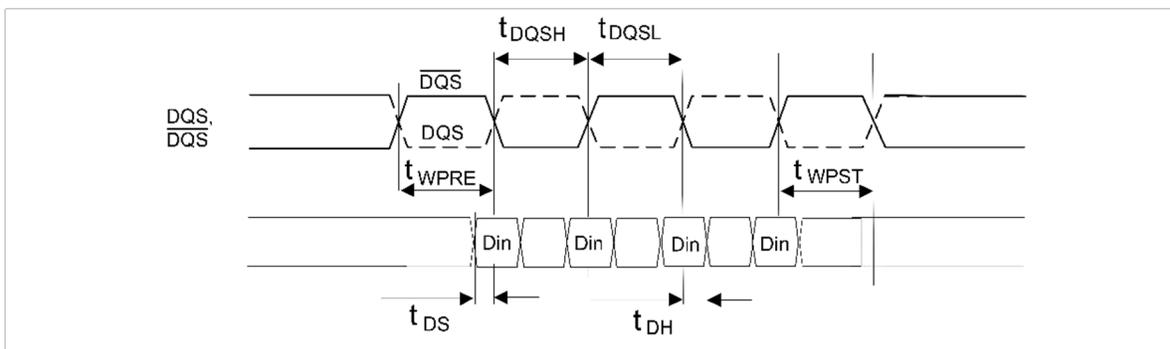

Burst Write Operation : RL = 5 (AL = 2, CI = 3), WL = 4, BL = 4
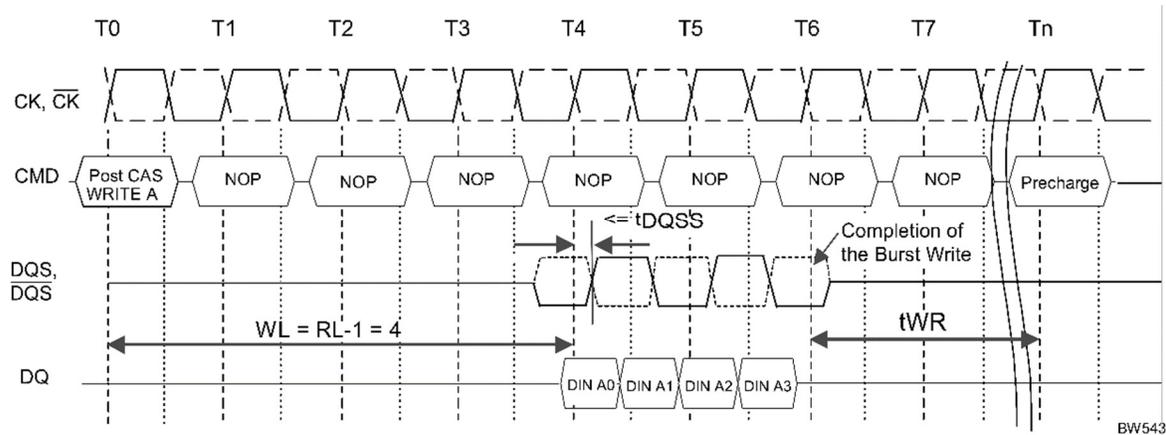

Burst Write followed by Burst Read : RL = 5 (AI = 2, CL = 3), WL = 4, t_{WRT} = 2, BL = 4
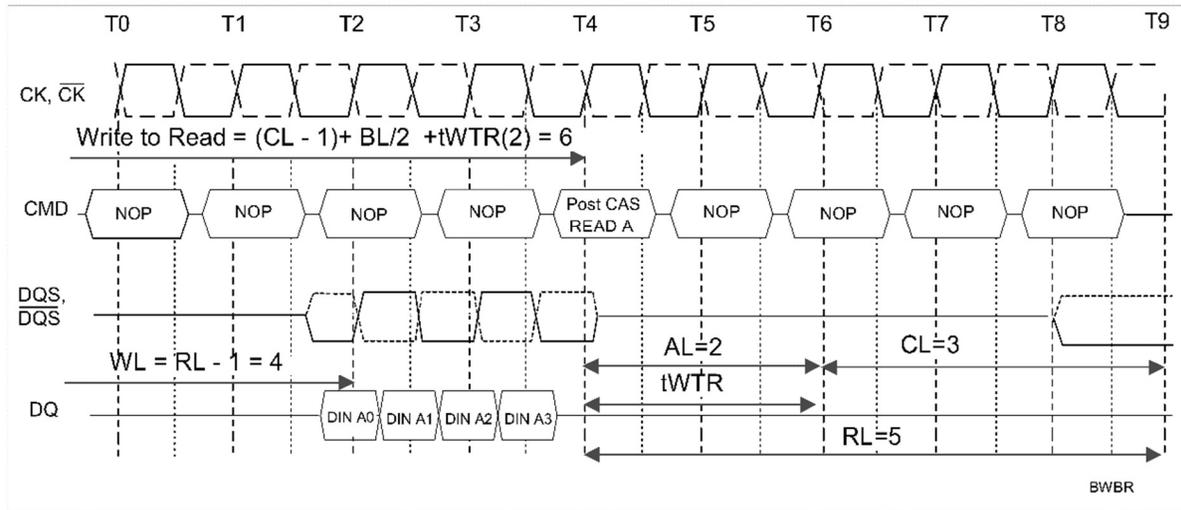

Burst Write Operation : RL = 3 (AL = 0, CL = 3), WL = 2, BL = 4
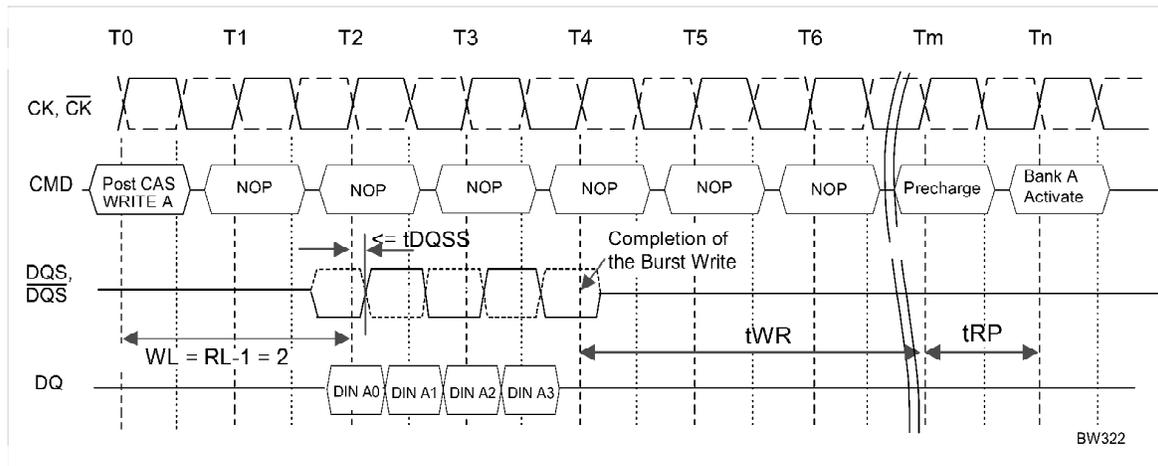

The minimum number of clocks from the burst write command to the burst read command is

$$(CL - 1) + BL/2 + t_{WTR}$$

where t_{WTR} is the write-to-read turn-around time t_{WTR} expressed in clock cycles. The t_{WTR} is not a write recovery time (t_{WR}) but the time required to transfer 4 bit write data from the input buffer into sense amplifiers in the array.

Seamless Burst Write Operation : RL = 5, WL = 4, BL = 4
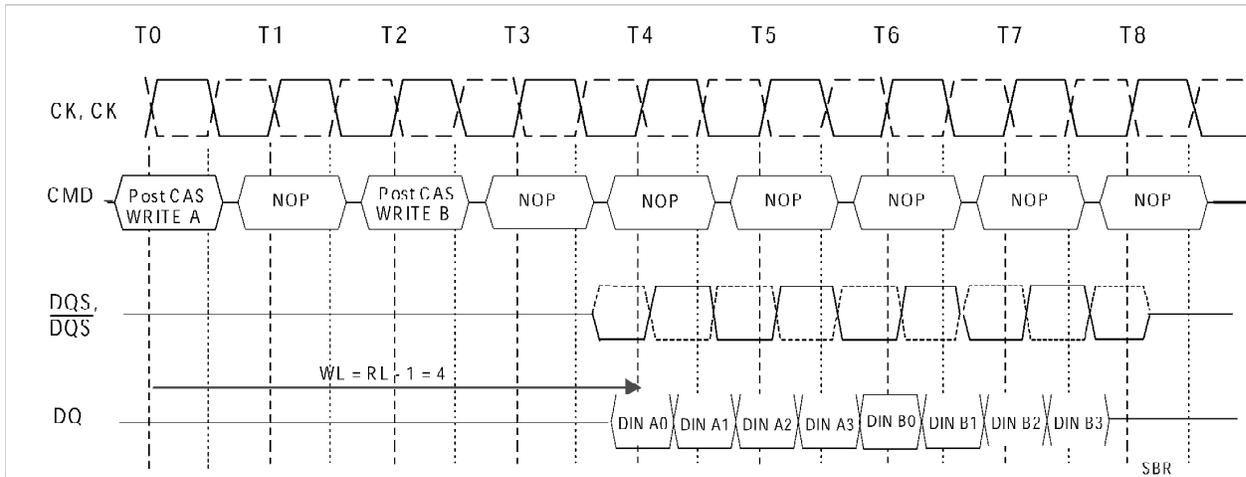

The seamless burst write operation is supported by enabling a write command every BL / 2 number of clocks. This operation is allowed regardless of same or different banks as long as the banks are activated.

Seamless Burst Write Operation : RL = 3, WL = 2, BL = 8, non-interrupting
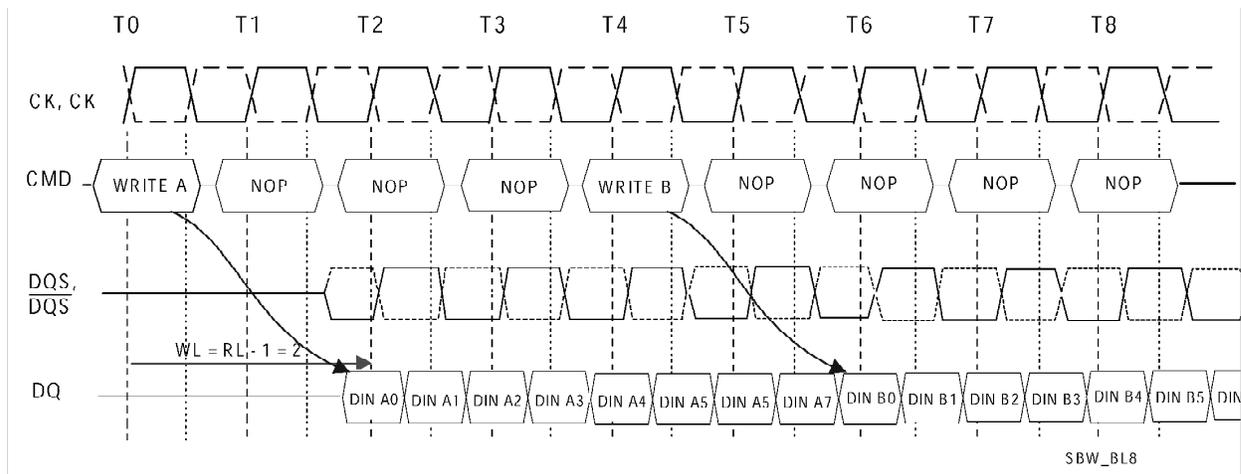

The seamless, non interrupting 8-bit burst write operation is supported by enabling a write command at every BL / 2 number of clocks. This operation is allowed regardless of same or different banks as long as the banks are activated.

Write Data Mask

One write data mask input (DM) for x8 components are supported on DDR2 SDRAMs, consistent with the implementation on DDR SDRAMs. It has identical timings on write operations as the data bits, and though used in a uni-directional manner,

is internally loaded identically to data bits to insure matched system timing. Data mask is not used during read cycles. If DM is high during a write burst coincident with the write data, the write data bit is not written to the memory. For x8 components the DM function is disabled, when RDQS / $\overline{RDQS}$ are enabled by EMRS.

Write Data Mask Timing
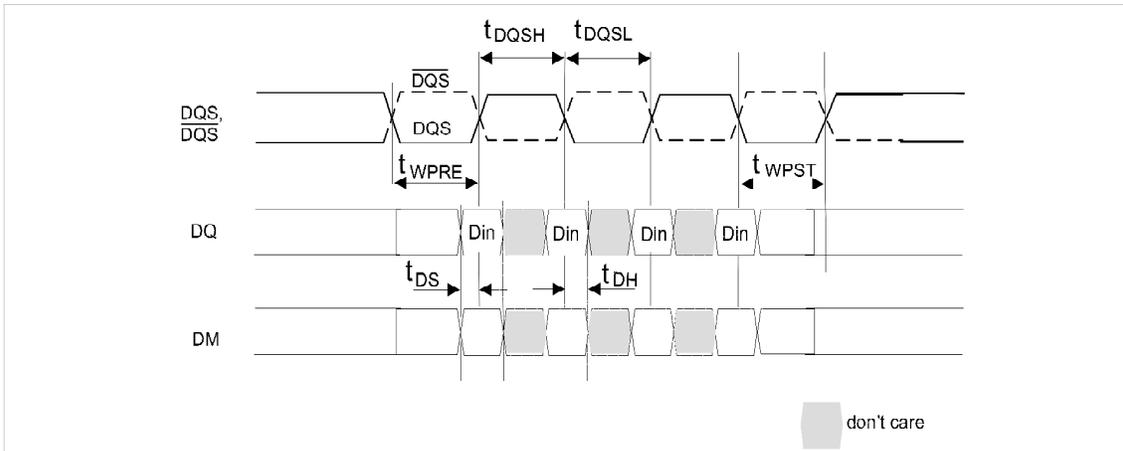

Burst Write Operation with Data Mask : RL = 3 (AL = 0, CL = 3), WL = 2, t_{WR} = 3, BL = 4
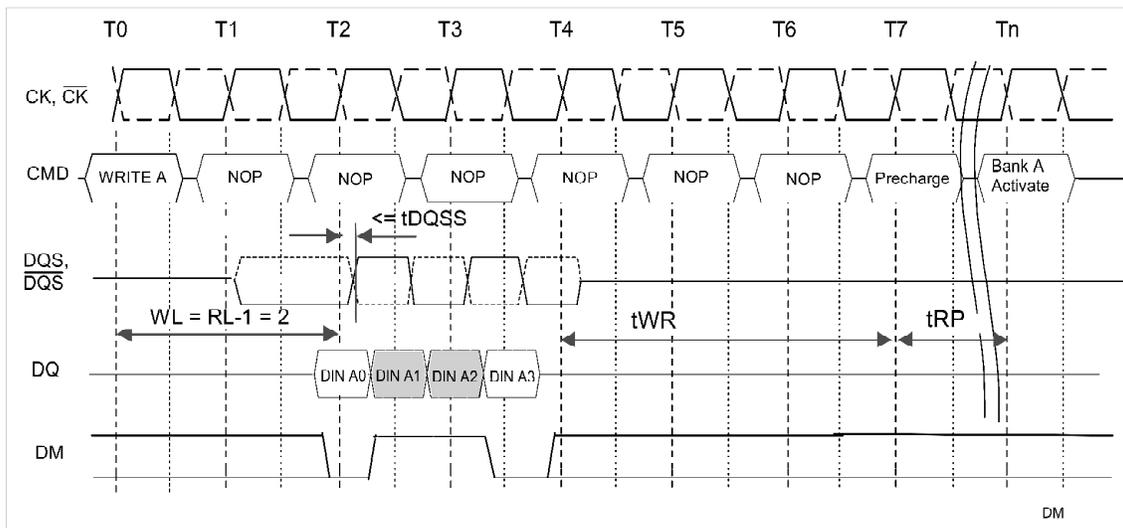

Burst Interruption

Interruption of a read or write burst is prohibited for burst length of 4 and only allowed for burst length of 8 under the following conditions:

1. A Read Burst of 8 can only be interrupted by another Read command. Read burst interruption by a Write or Precharge Command is prohibited.

2. A Write Burst of 8 can only be interrupted by another Write command. Write burst interruption by a Read or Precharge Command is prohibited.

3. Read burst interrupt must occur exactly two clocks after the previous Read command. Any other Read burst interrupt timings are prohibited.

4. Write burst interrupt must occur exactly two clocks after the previous Write command. Any other Read burst interrupt timings are prohibited.

5. Read or Write burst interruption is allowed to any bank inside the DDR2 SDRAM.

6. Read or Write burst with Auto-Precharge enabled is not allowed to be interrupted.

7. Read burst interruption is allowed by a Read with Auto-Precharge command.

8. Write burst interruption is allowed by a Write with Auto-Precharge command.

9. All command timings are referenced to burst length set in the mode register. They are not referenced to the actual burst. For example, Minimum Read to Precharge timing is $AL + BL/2$ where BL is the burst length set in the mode register and not the actual burst (which is shorter because of interrupt). Minimum Write to Precharge timing is $WL + BL/2 + t_{WR}$, where t_{WR} starts with the rising clock after the un-interrupted burst end and not form the end of the actual burst end.

Read Burst Interrupt Timing Example : (CL = 3, AL = 0, RL = 3, BL = 8)
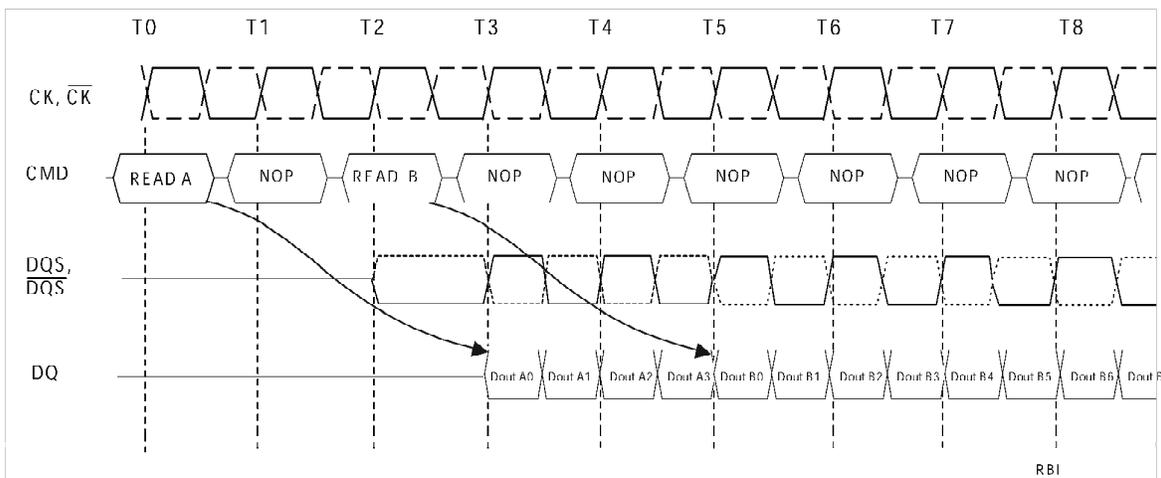

Write Burst Interrupt Timing Example : (CL = 3, AL = 0, WL = 2, BL = 8)
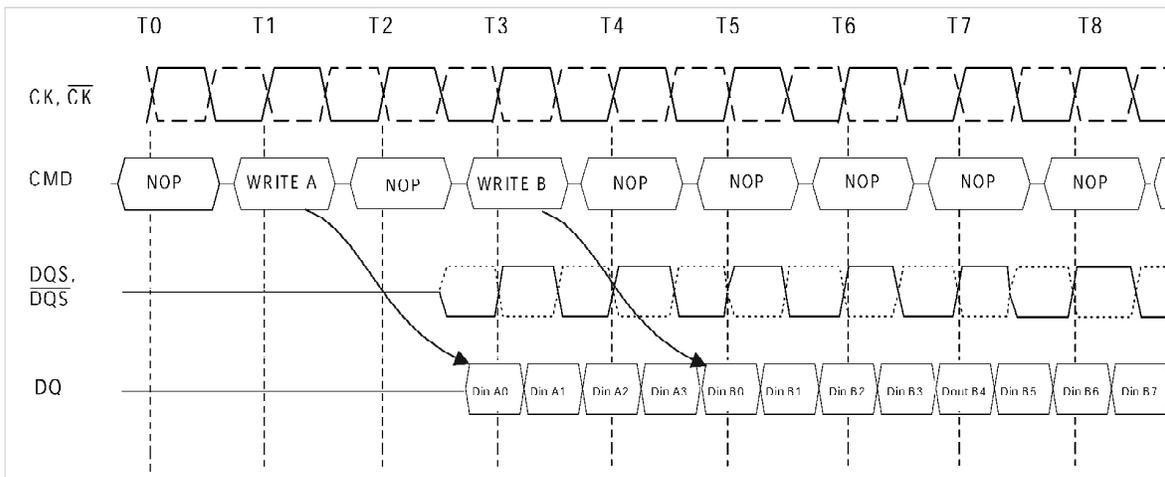

Precharge Command

The Precharge Command is used to precharge or close a bank that has been activated. The Precharge Command is triggered when $\overline{CS}$, $\overline{RAS}$ and $\overline{WE}$ are low and $\overline{CAS}$ is high at the rising edge of the clock. The Pre-charge Command can be used to precharge each bank independently or all banks simultaneously. Four address bits A10, BA1 and BA0 are used to define which bank to precharge when the command is issued.

Bank Selection for Precharge by Address Bits

A10	BA2	BA1	BA0	Precharge Bank(s)
LOW	LOW	LOW	LOW	Bank 0 only
LOW	LOW	LOW	HIGH	Bank 1 only
LOW	LOW	HIGH	LOW	Bank 2 only
LOW	LOW	HIGH	HIGH	Bank 3 only
LOW	HIGH	LOW	LOW	Bank 4 only
LOW	HIGH	LOW	HIGH	Bank 5 only
LOW	HIGH	HIGH	LOW	Bank 6 only
LOW	HIGH	HIGH	HIGH	Bank 7 only
HIGH	Don't Care	Don't Care	Don't Care	All Banks

Burst Read Operation Followed by a Precharge

The following rules apply as long as the t_{RTP} timing parameter - Internal Read to Precharge Command delay time - is less or equal two clocks, which is the case for operating frequencies less or equal 266 MHz (DDR2 400 and 533 speed sorts):

Minimum Read to Precharge command spacing to the same bank = AL + BL/2 clocks. For the earliest possible precharge, the precharge command may be issued on the rising edge which is "Additive Latency (AL) + BL/2 clocks" after a Read Command, as long as the minimum t_{RAS} timing is satisfied.

A new bank active command may be issued to the same bank if the following two conditions are satisfied simultaneously:

(1) The $\overline{RAS}$ precharge time (t_{RP}) has been satisfied from the clock at which the precharge begins.

(2) The $\overline{RAS}$ cycle time ($t_{RC(min)}$) from the previous bank activation has been satisfied.

For operating frequencies higher than 266 MHz, t_{RTP} becomes > 2 clocks and one additional clock cycle has to be added for the minimum Read to Precharge command spacing, which now becomes AL + BL/2 + 1 clocks.

Burst Read Operation Followed by Precharge : RL = 4 (AL = 1, CL = 3), BL = 4, t_{RTP} <= 2clocks
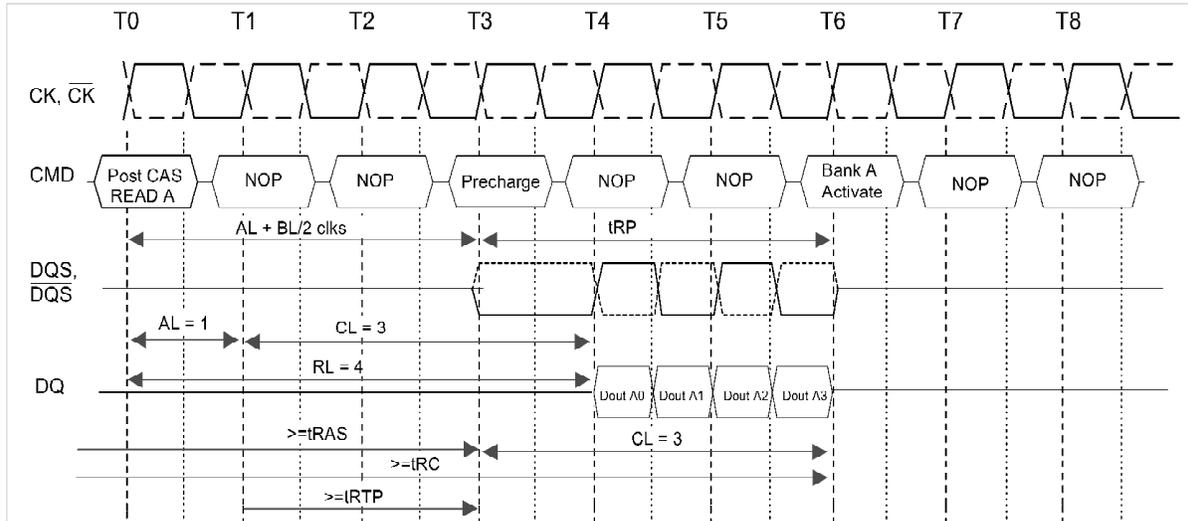

Burst Read Operation Followed by Precharge : RL = 4 (AL = 1, CL = 3), BL = 8, t_{RTP} <= 2clocks

first 4-bit prefetch   second 4-bit prefetch

BR-P413(8)
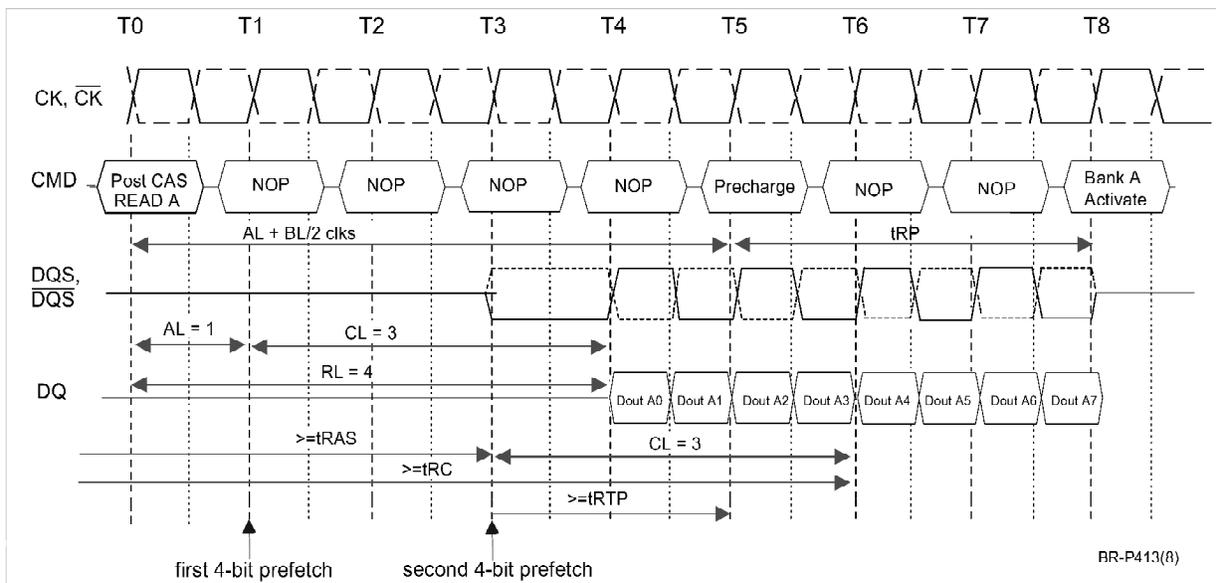

Burst Read Operation Followed by Precharge : RL = 5 (AL = 2, CL = 3), BL = 4, t$_{RTP}$ <= 2clocks
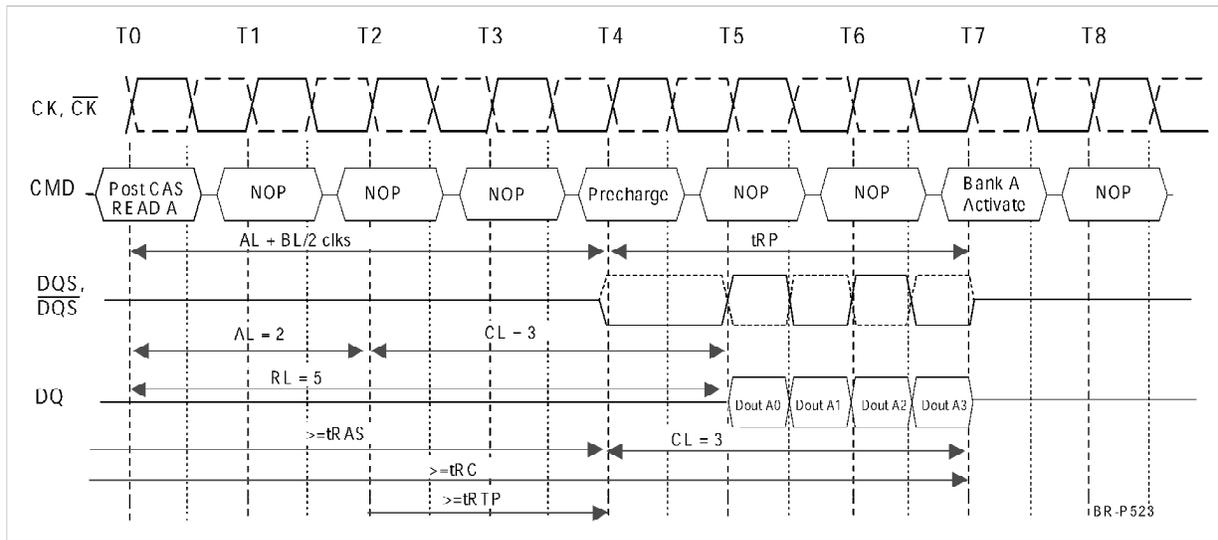

Burst Read Operation Followed by Precharge : RL = 6 (AL = 2, CL = 3), BL = 4, t$_{RTP}$ <= 2clocks
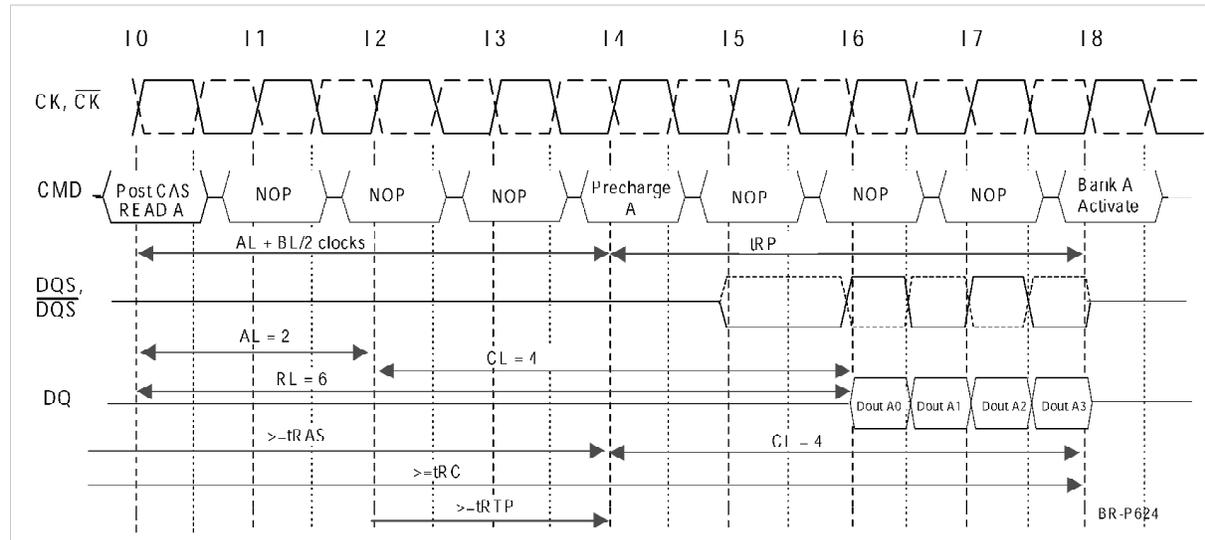

Burst Read Operation Followed by Precharge : RL = 4 (AL = 0, CL = 4), BL = 8, t_{RTP} > 2clocks
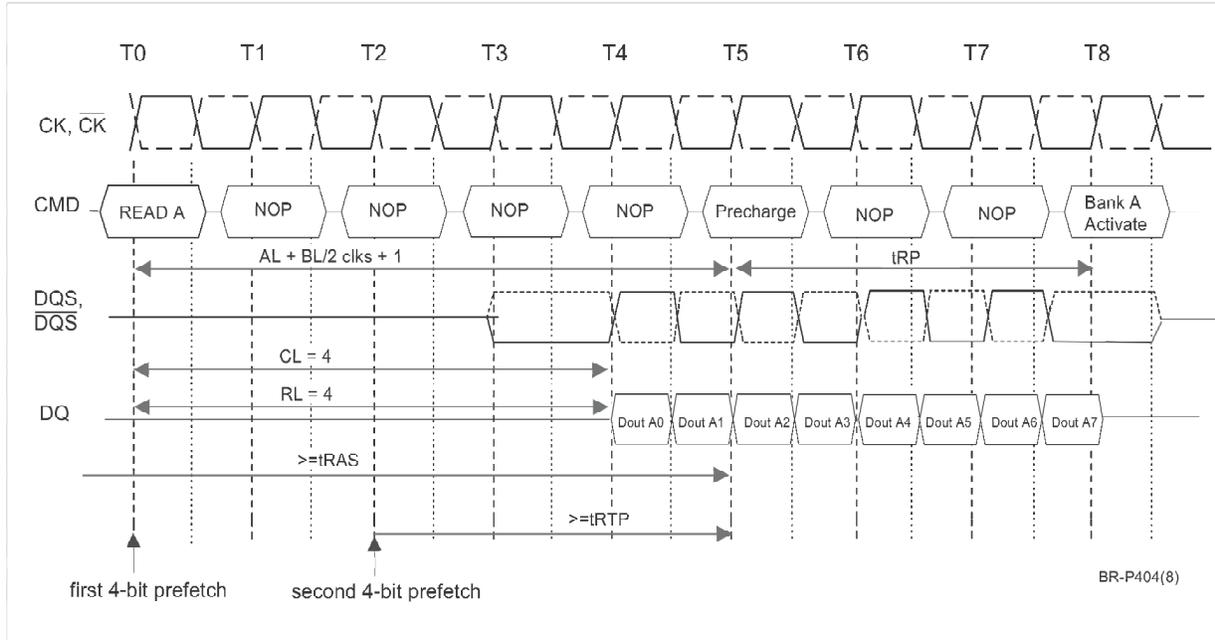

Burst Write followed by Precharge

Minimum Write to Precharge command spacing to the same bank = **WL + BL/2 + tWR**. For write cycles, a delay must be satisfied from the completion of the last burst write cycle until the Precharge command can be issued. This delay is known as a write recovery time (t_{WR}) referenced from the completion of the burst write to the Precharge command. No Precharge command should be issued prior to the t_{WR} delay, as DDR2 SDRAM does not support any burst interrupt by a Precharge command. t_{WR} is an analog timing parameter (see the AC table in this datasheet) and is not the programmed value for t_{WR} in the MRS.

Burst Write followed by Precharge : WL = (RL – 1) = 3, BL = 4, t_{WR} = 3
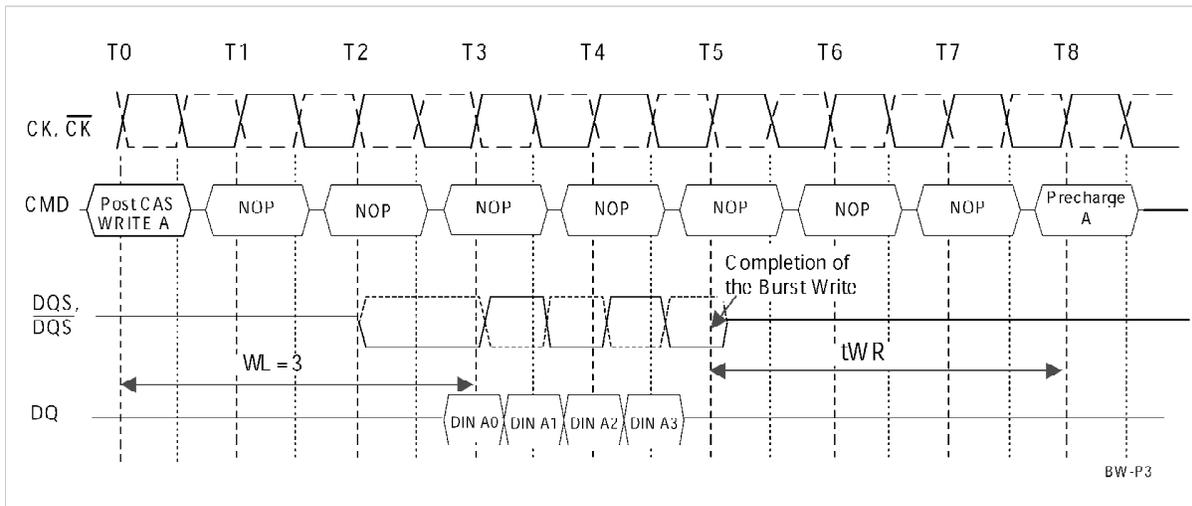

Burst Write followed by Precharge : WL = (RL – 1) = 4, BL = 4, t_{WR} = 3
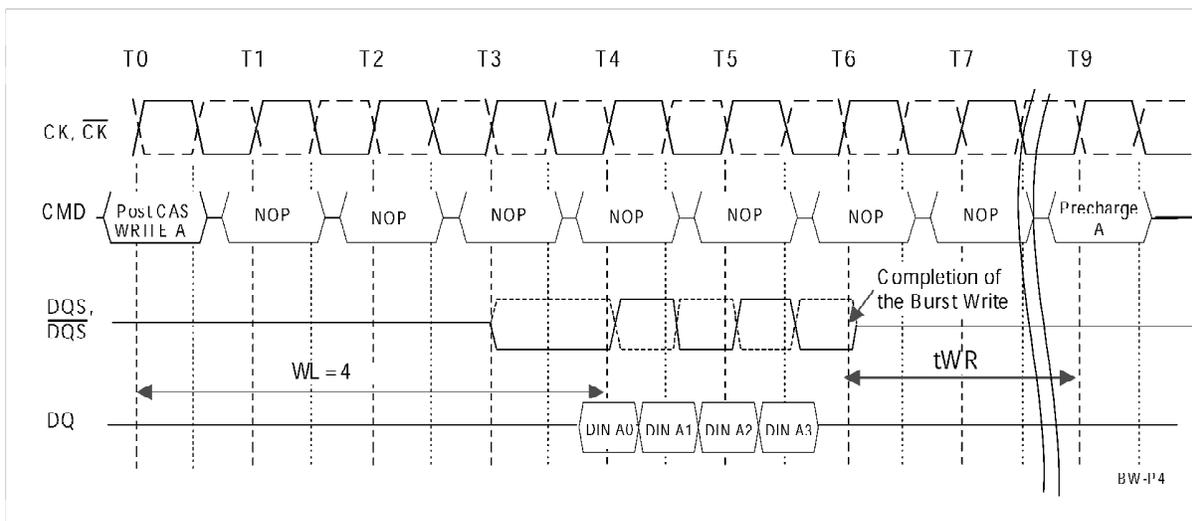

Auto-Precharge Operation

Before a new row in an active bank can be opened, the active bank must be precharged using either the Precharge Command or the Auto-Precharge function. When a Read or a Write Command is given to the DDR2 SDRAM, the $\overline{CAS}$ timing accepts one extra address, column address A10, to allow the active bank to automatically begin precharge at the earliest possible moment during the burst read or write cycle. If A10 is low when the Read or Write Command is issued, then normal Read or Write burst operation is executed and the bank remains active at the completion of the burst sequence. If A10 is high when the Read or Write Command is issued, then the Auto-Precharge function is enabled. During Auto-Precharge, a Read Command will execute as normal with the exception that the active bank will begin to precharge internally on the rising edge which is CAS Latency (CL) clock cycles before the end of the read burst. Auto-Precharge is also implemented for Write Commands. The precharge operation engaged by the Auto-Precharge command will not begin until the last data of the write burst sequence is properly stored in the memory array. This feature allows the pre-charge operation to be partially or completely hidden during burst read cycles (dependent upon $\overline{CAS}$ Latency) thus improving system performance for random data access. The RAS lockout circuit internally delays the Precharge operation until the array restore operation has been completed so that the Auto-Precharge command may be issied with any read or write command.

Burst Read with Auto-Precharge

If A10 is high when a Read Command is issued, the Read with Auto-Precharge function is engaged. The DDR2 SDRAM starts an Auto-Precharge operation on the rising edge which is (AL + BL /2) cycles later from the Read with AP command if $t_{RAS(min)}$ and t_{RTP} are satisfied. If $t_{RAS(min)}$ is not satisfied at the edge, the start point of Auto-Precharge operation will be delayed until $t_{RAS(min)}$ is satisfied. If $t_{RTP(min)}$ is not satisfied a t the edge, the start point of Auto-precharge operation will be delayed until $t_{RTP(min)}$ is satisfied.

In case the internal precharge is pushed out by t_{RTP}, t_{RP} starts at the point where the internal precharge happens (not a t the next rising clock edge after this e vent). So for BL = 4 the minimum time from Read with Auto-Precharge to the next Activate command becomes AL + t_{RTP} + t_{RPF} or BL = 8 the time from Read with Auto-Precharge to the next Activate command is AL + 2 + t_{RTP} + t_{RP}. Note that both parameters t_{RTP} and t_{RP} have to be rounded up to the next integer value. In any event internal precharge does not start earlier than two clocks after the last 4-bit prefetch.

A new bank active (command) may be issued to the same bank if the following two conditions are satisfied simultaneously:

(1) The $\overline{RAS}$ precharge time (t_{RP}) has been satisfied from the clock at which the Auto-Precharge begins.

(2) The $\overline{RAS}$ cycle time (t_{RC}) from the previous bank activation has been satisfied.

Burst Read with Auto-Precharge followed by an activation to the Same Bank (t_{RC} Limit)
**RL = 5 (AL = 2, CL = 3), BL = 4, t_{RTP} <= 2 clocks**
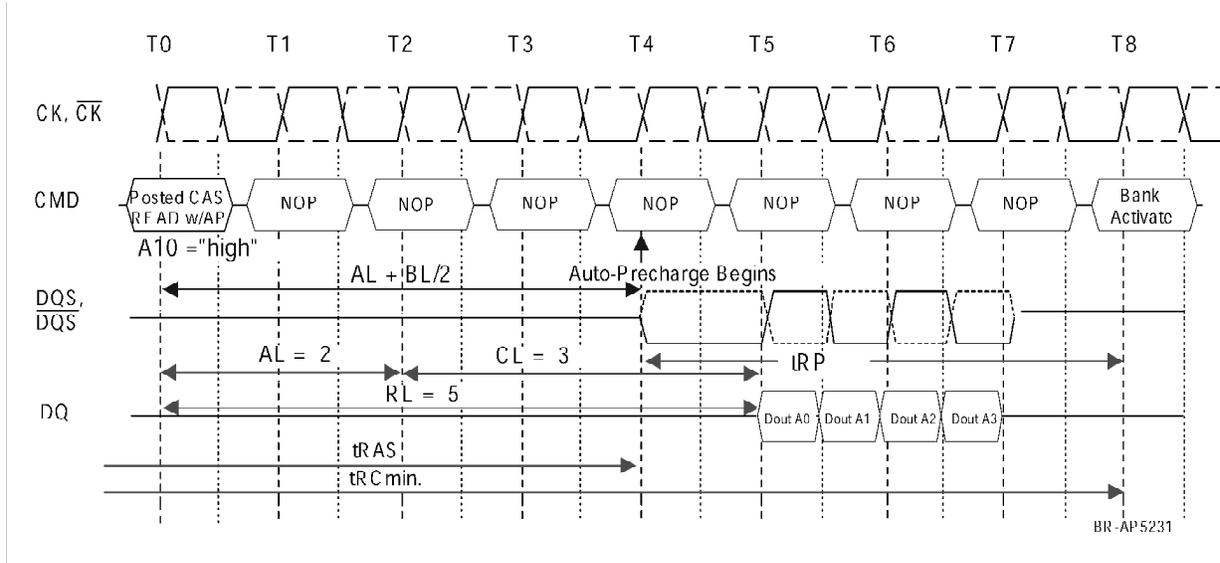

Burst Read with Auto-Precharge followed by an activation to the Same Bank (t_{RAS} Limit)
**RL = 5 (AL = 2, CL = 3), BL = 4, t_{RTP} <= 2 clocks**
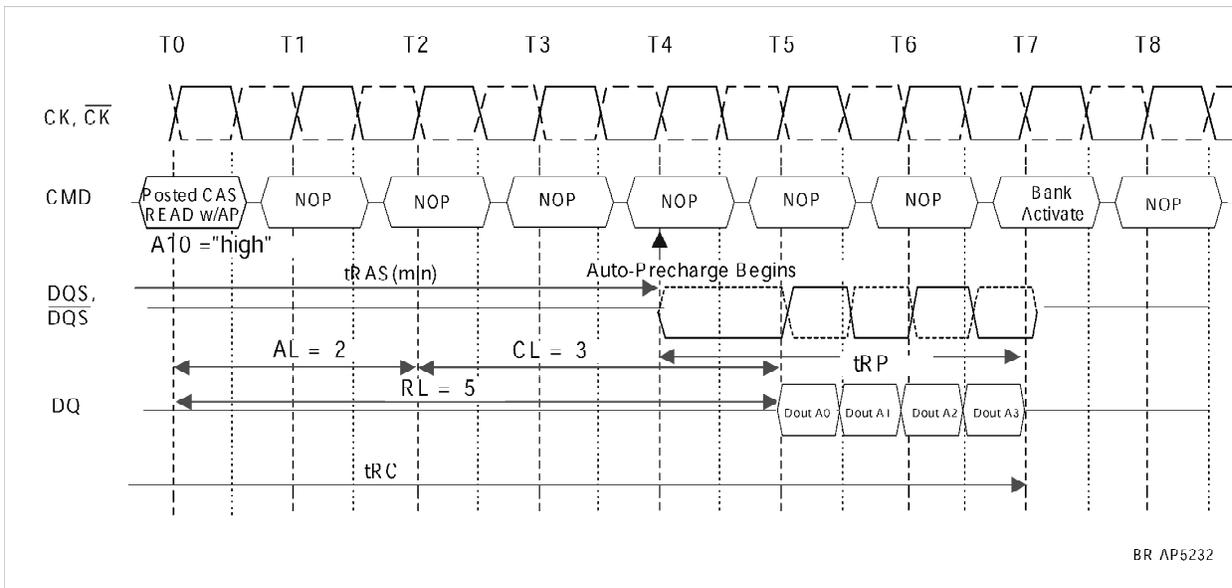

Burst Read with Auto-Precharge followed by an Activation to the Same Bank:
RL = 4 (AL = 1, CL = 3), BL = 8, t_{RTP} <= 2clocks
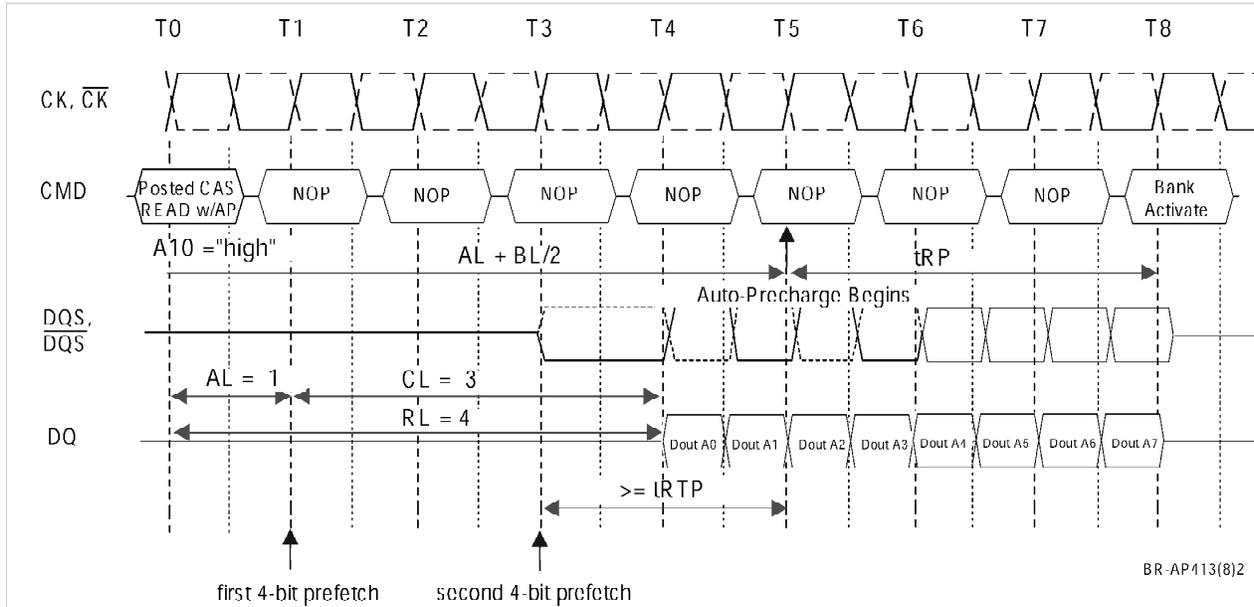

Burst Read with Auto-Precharge followed by an Activation to the Same Bank:
**RL = 4 (AL = 1, CL = 3), BL = 4, t_{RTP} > 2clocks**
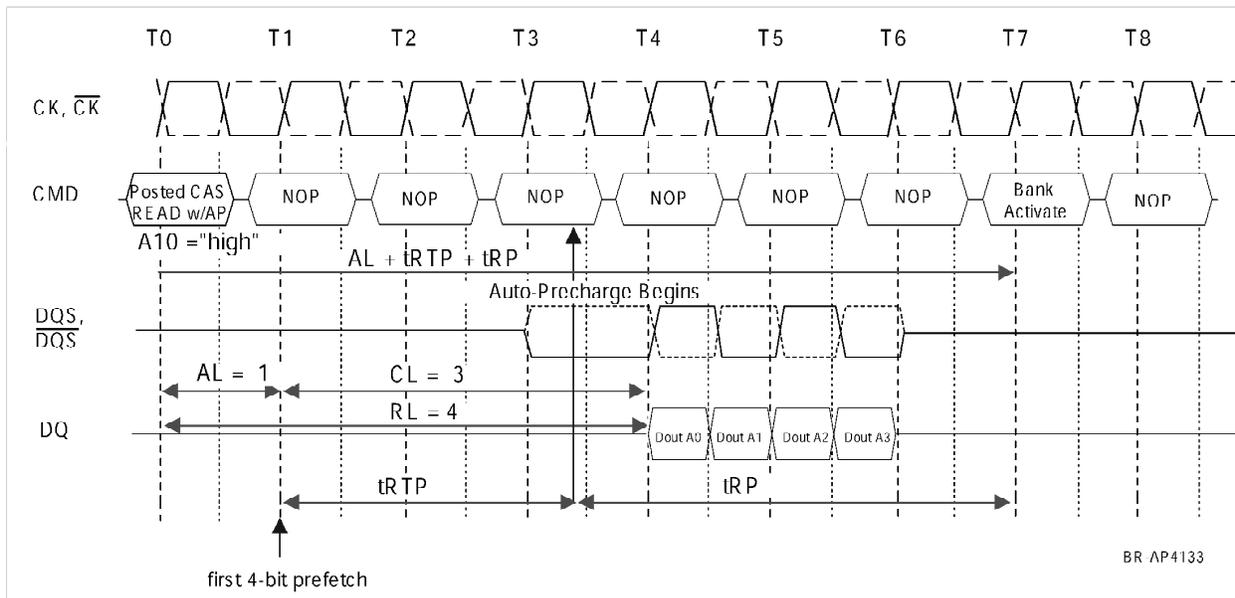

Burst Write with Auto-Precharge

If A10 is high when a Write Command is issued, the Write with Auto-Precharge function is engaged. The DDR2 SDRAM automatically begins precharge operation after the completion of the write burst plus the write recovery time delay (WR), programmed in the MRS register, as long as t_{RAS} is satisfied. The bank undergoing Auto-Precharge from the completion of the write burst may be reactivated if the following two conditions are satisfied.

(1)   The last data-in to bank activate delay time ($t_{DAL} = WR + t_{RP}$) has been satisfied.
(2)   The RAS cycle time (t_{RC}) from previous bank activation has been satisified.

In DDR2 SDRAMs the write recovery time delay (WR) has to be programmed into the MRS mode register. As long as the analog t_{WR} timing parameter is not violated, WR can be programmed be twee n 2 and 6 clock cycles. Minimum Write to Activate command spacing to the same bank = $WL + BL/2 + t_{DAL}$.

Examples:

Burst Write with Auto-Precharge (t_{RC} Limit) : WL = 2, t_{DAL} = 6 (WR = 3, t_{RP} = 3), BL = 4
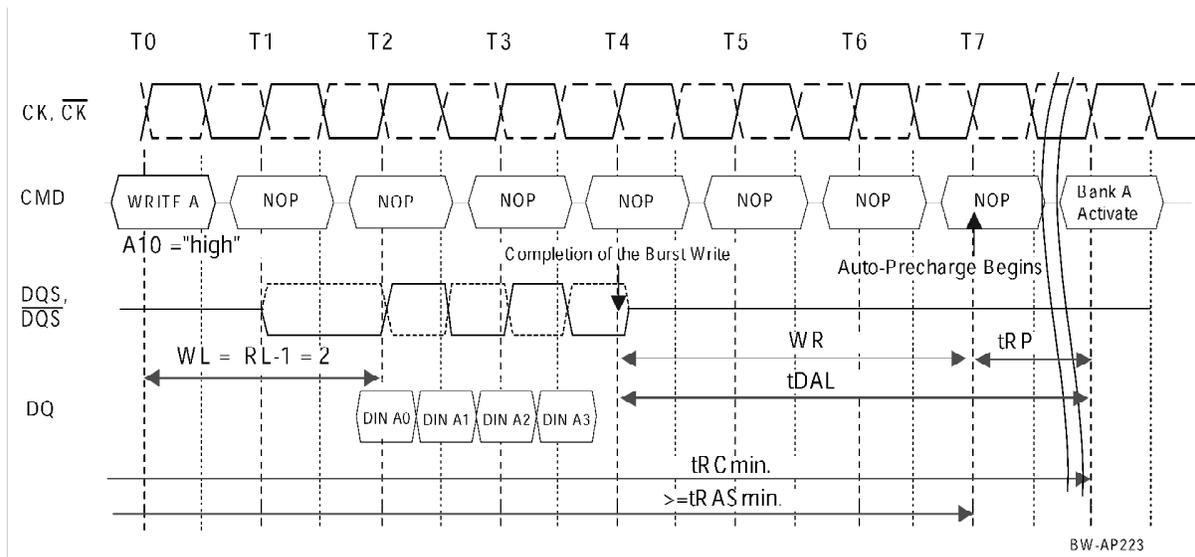

Burst Write with Auto-Precharge (WR + t$_{RP}$ Limit): WL = 4, t$_{DAL}$ = 6 (WR = 3, t$_{RP}$ = 3), BL = 4
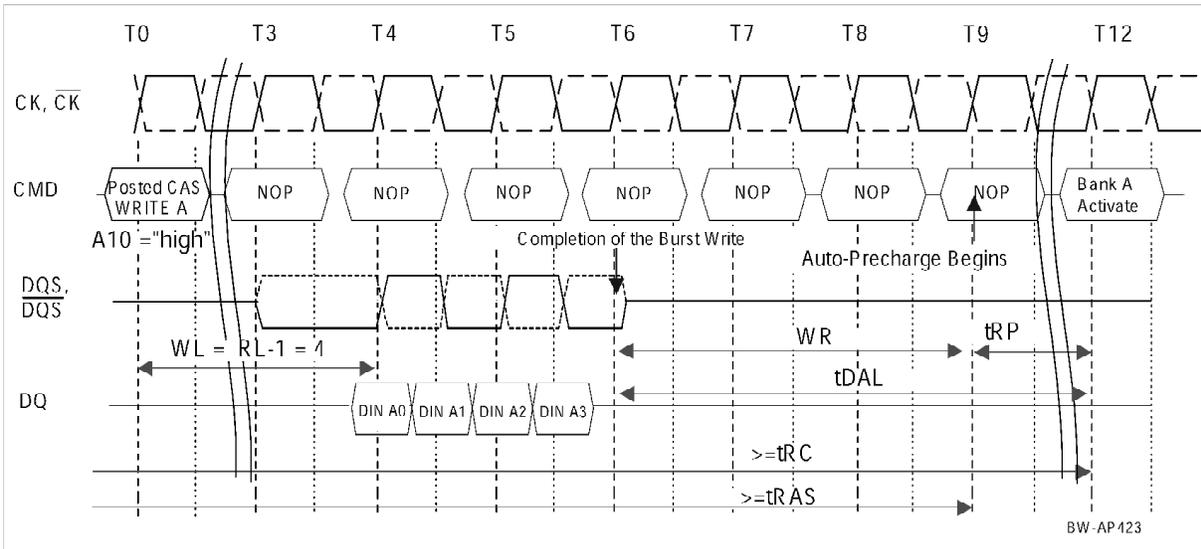

Concurrent Auto-Precharge

DDR2 devices support the "concurrent Auto-Precharge" feature. A read with Auto-Precharge enabled, or a write with Auto-Precharge enabled, may be followed by any command to the other bank, as long as that command does not interrupt the read or write data transfer, and all other related limitations (e.g. contention between Read data and Write data must be avoided externally and on the internal data bus.

The minimum delay from a read or write command with Auto-Precharge enabled, to a command to a different bank, is summarized in the table below. As defined, the WL = RL - 1 for DDR2 devices which allows the command gap and corresponding data gaps to be minimized.

From Command	To Command (Different bank, non-interrupting command)	Minimum Delay with Concurrent Auto-Pre-charge Support	Units
WRITE w/ AP	Read or Read w/ AP	$(CL-1) + (BL/2) + t_{WTR}$	t_{CK}
	Write or Write w/ AP	$BL/2$	t_{CK}
	Precharge or Activate	1	t_{CK}
READ w/ AP	Read or Read w/ AP	$BL/2$	t_{CK}
	Write or Write w/ AP	$BL/2 + 2$	t_{CK}
	Precharge or Activate	1	t_{CK}

Refresh

SDRAMs require a refresh of all rows in any rolling 64 ms interval. Each refresh is generated in one of two ways: by an explicit Auto-Refresh command, or by an internally timed event in Self-Refresh mode. Dividing the number of device rows into the rolling 64 ms interval defined the average refresh interval t_{REFI}, which is a guideline to controllers for distributed refresh timing. For example, a 512Mbit DDR2 SDRAM has 8192 rows resulting in a t_{REFI} of 7.8 µs.

Auto-Refresh Command

Auto-Refresh is used during normal operation of the DDR2 SDRAMs. This command is nonpersistent, so it must be issued each time a refresh is required. The refresh addressing is generated by the internal refresh controller. This makes the address bits "Don't Care" during an Auto-Refresh command. The DDR2 SDRAM requires Auto-Refresh cycles at an average periodic interval of $t_{REFI(max)}$.

When $\overline{CS}$, $\overline{RAS}$ and $\overline{CAS}$ are held low and $\overline{WE}$ high at the rising edge of the clock, the chip enters the Auto-Refresh mode. All banks of the SDRAM must be precharged and idle for a minimum of the Precharge time (t_{RP}) before the Auto-Refresh Command can be applied. An internal address counter supplies the addresses during the refresh cycle. No control of the external address bus is required once this cycle has started.

When the refresh cycle has completed, all banks of the SDRAM will be in the precharged (idle) state. A delay between the Auto-Refresh Command and the next Activate Command or subsequent Auto-Refresh Command must be greater than or equal to the Auto-Refresh cycle time (t_{RFC}).

To allow for improved efficiency in scheduling and switching between tasks, some flexibility in the absolute refresh interval is provided. A maximum of eight Auto-Refresh commands can be posted to any given DDR2 SDRAM, meaning that the maximum absolute interval between any Auto-Refresh command and the next Auto-Refresh command is 9 * t_{REFI}.
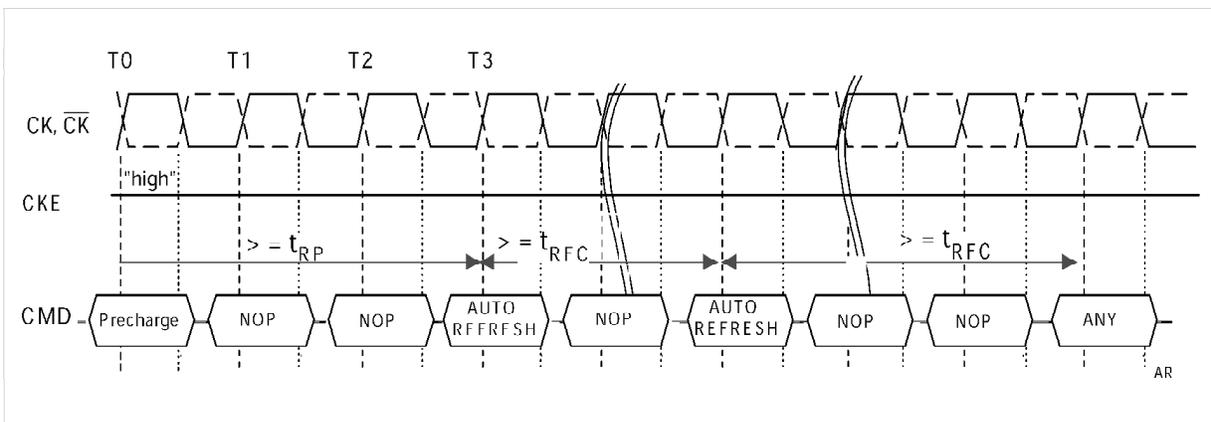

Self-Refresh Command

The Self -Refresh command can be used to retain data, even if the rest of the system is powered down. When in the Self-Refresh mode, the DDR2 SDRAM retains data without external clocking.

The DDR2 SDRAM device has a built-in timer to accommodate Self-Refresh operation. The Self-Refresh Command is defined by having $\overline{CS}$, $\overline{RAS}$, $\overline{CAS}$ and CKE held low with $\overline{WE}$ high at the rising edge of the clock. ODT must be turned off before issuing Self Refresh command, by either driving ODT pin low or using EMRS command. Once the command is registered, CKE must be held low to keep the device in Self-Refresh mode. When the DDR2 SDRAM has entered Self-Refresh mode, all of the external control signals, except CKE, are disabled. The clock is internally disabled during Self-Refresh Operation to save power. The user may change the external clock frequency or halt the external clock one clock after Self-Refresh entry is registered, however, the clock must be restarted and stable before the device can exit Self-Refresh operation.

Once Self-Refresh Exit command is registered, a delay equal or longer than the t_{XSNR} or t_{XSRD} must be satisfied before a valid command can be issued to the device. CKE must remain high for the entire Self-Refresh exit period (t_{XSNR} or t_{XSRD}) for proper operation. NOP or DESELECT commands must be registered on each positive clock edge during the Self-Refresh exit interval. Since the ODT function is not supported during Self-Refresh operation, ODT has to be turned off before entering Self-Refresh Mode (t_{AOFD}) and can be turned on again when the t_{XSRD} timing is satisfied.
 * = Device must be in the "All banks idle" state to entering Self Refresh mode.
 ODT must be turned off prior to entering Self Refresh mode.
 tXSRD has to be satisfied for a Read or a Read with Auto-Precharge command.
 tXSNR has to be satisfied for any command except a Read or a Read with Auto-Precharge command.

Power-Down

Power-down is synchronously entered when CKE is registered low along with NOP or Deselect command. No read or write operation may be in progress when CKE goes low. These operations are any of the following: read burst or write burst and recovery. CKE is allowed to go low while any of other operations such as row activation, precharge or autoprecharge, mode register or extended mode register command time, or autorefresh is in progress. The DLL should be in a locked state when power-down is entered. Otherwise DLL should be reset after exiting power-down mode for proper read operation.

If power-down occurs when all banks are precharged, this mode is referred to as *Precharge Power-down*; if power-down occurs when there is a row active in any bank, this mode is referred to as *Active Power-down*. For *Active Power-down* two different power saving modes can be selected within the MRS register, address bit A12. When A12 is set to "low" this mode is referred as "standard active power-down mode" and a fast power-down exit timing defined by the t_{XARD} timing parameter can be used. When A12 is set to "high" this mode is referred as a power saving "low power active power-down mode". This mode takes longer to exit from the power-down mode and the t_{XARDS} timing parameter has to be satisfied.

Entering power-down deactivates the input and output buffers, excluding CK, $\overline{CK}$, ODT and CKE. Also the DLL is disabled upon entering precharge power-down or slow exit active power-down, but the DLL is kept enabled during fast exit active power-down. In power-down mode, CKE low and a stable clock signal must be maintained at the inputs of the DDR2 SDRAM, and all other input signals are "Don't Care". Power-down duration is limited by 9 times t_{REFI} of the device.

The power-down state is synchronously exited when CKE is registered high (along with a NOP or Deselect command). A valid, executable command can be applied with power-down exit latency, t_{XP}, t_{XARD} or t_{XARDS}, after CKE goes high. Power-down exit latencies are defined in the AC spec table of this data sheet.

Power-Down Entry

Active Power-down mode can be entered after an activate command. *Precharge Power-down* mode can be entered after a precharge, precharge-all or internal precharge command. It is also allowed to enter power-mode after an Auto-Refresh command or MRS / EMRS command when t_{MRD} is satisfied.

Active Power-down mode entry is prohibited as long as a Read Burst is in progress, meaning CKE should be kept high until the burst operation is finished. Therefore Active Power-Down mode entry after a Read or Read with Auto-Precharge command is allowed after RL + BL/2 is satisfied.

Active Power-down mode entry is prohibited as long as a Write Burst and the internal write recovery is in progress. In case of a write command, active power-down mode entry is allowed when WL + BL/2 + t_{WTR} is satisfied.

In case of a write command with auto-precharge, power-down mode entry is allowed after the internal pre-charge command has been executed, which is WL + BL/2 + WR starting from the write with auto-precharge command. In case the DDR2 SDRAM enters the *Precharge Power-down* mode.

Active Power-Down Mode Entry and Exit after an Activate Command

note: Active Power-Down mode exit timing tXARD ("fast exit") or tXARDS ("slow exit") depends on the programmed state in the MRS, address bit A12.
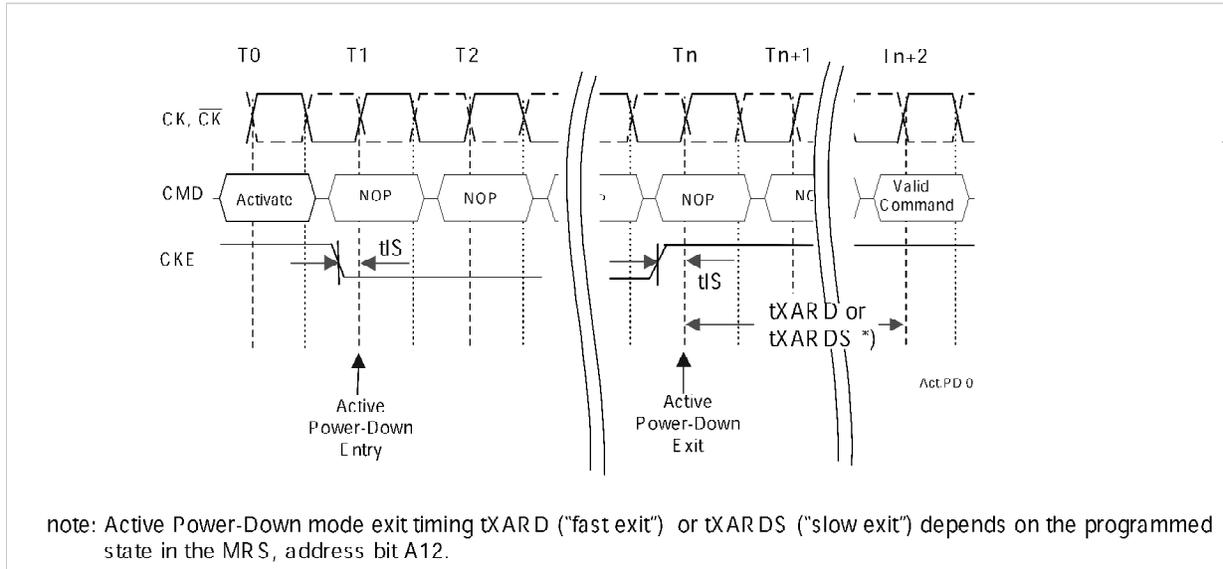

Active Power-Down Mode Entry and Exit after a Read Burst: RL = 4 (AL = 1, CL = 3). BL = 4

note: Active Power-Down mode exit timing tXARD ("fast exit") or tXARDS ("slow exit") depends on the programmed state in the MRS, address bit A12.
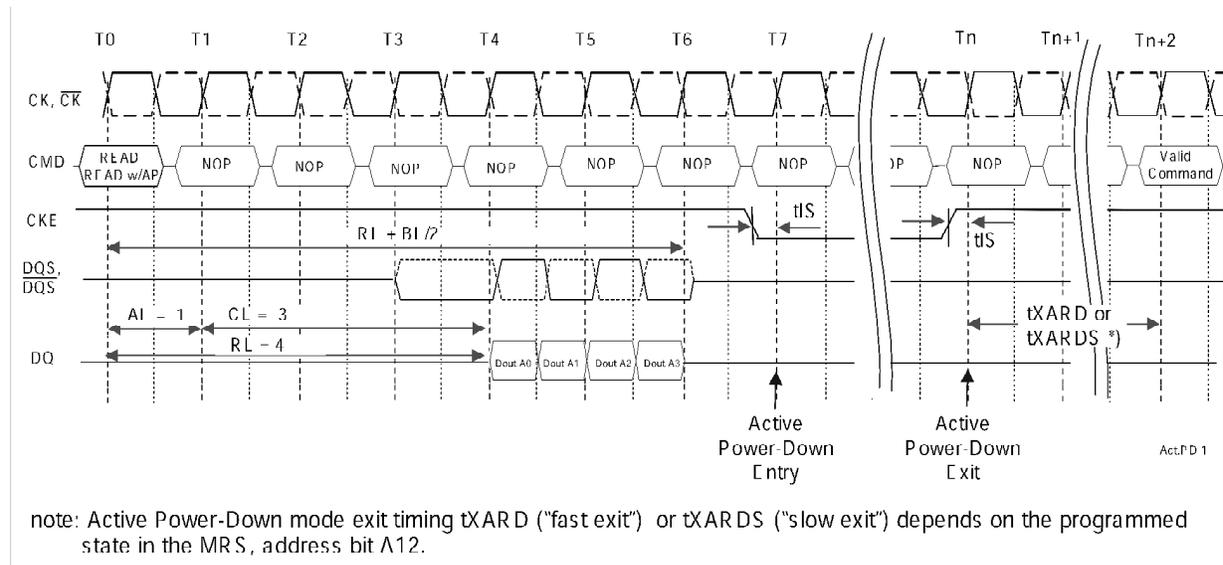

**Active Power-Down Mode Entry and Exit after a Write Burst: WL = 2, t_{WTR} = 2, BL = 4**

note: Active Power-Down mode exit timing tXARD ("fast exit") or tXARDS ("slow exit") depends on the programmed state in the MRS, address bit A12.

Precharge Power Down Mode Entry and Exit

*) "Precharge" may be an external command or an internal precharge following Write with AP.
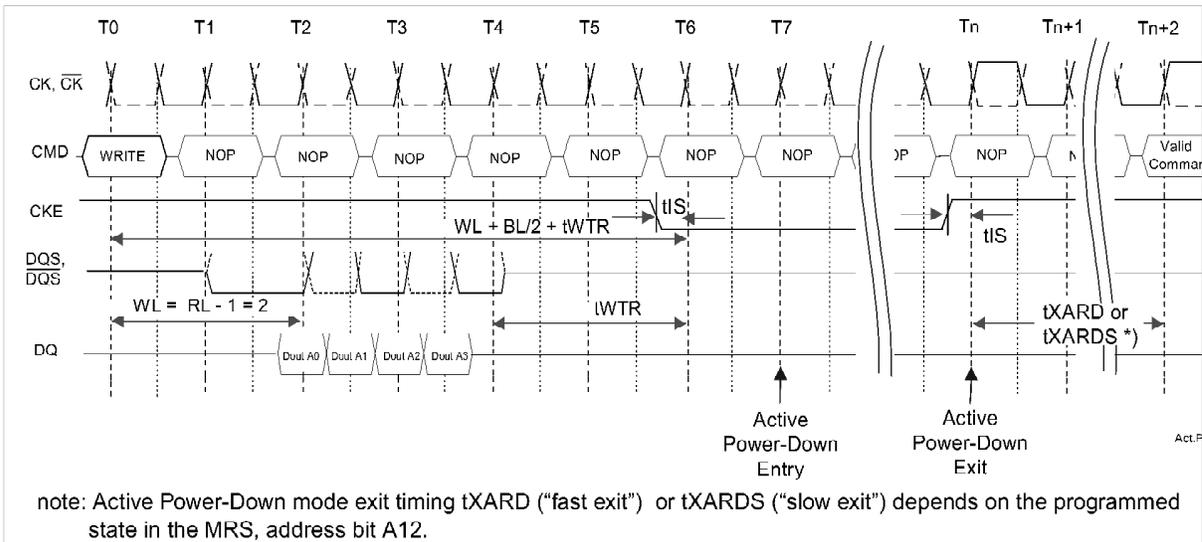

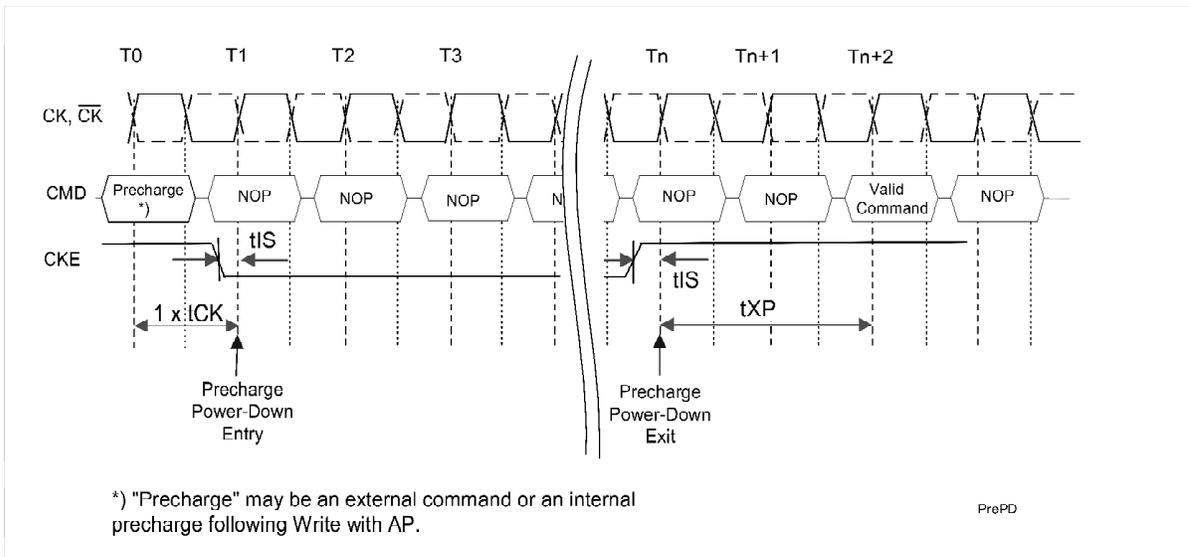

No Operation Command

The No Operation Command should be used in cases when the SDRAM is in a idle or a wait state. The purpose of the No Operation Command is to prevent the SDRAM from registering any unwanted commands between operations. A No Operation Command is registered when $\overline{CS}$ is low with $\overline{RAS}$, $\overline{CAS}$, and $\overline{WE}$ held high at the rising edge of the clock. A No Operation Command will not terminate a previous operation that is still executing, such as a burst read or write cycle.

Deselect Command

The Deselect Command performs the same function as a No Operation Command. Deselect Command occurs when $\overline{CS}$ is brought high, the $\overline{RAS}$, $\overline{CAS}$, and $\overline{WE}$ signals become don't care.

Input Clock Frequency Change

During operation the DRAM input clock frequency can be changed under the following conditions:

a) During Self-Refresh operation

b) DRAM is in precharged power-down mode and ODT is completely turned off.

The DDR2-SDRAM has to be in precharged power-down mode and idle. ODT must be already turned off and CKE must be at a logic "low" state. After a minimum of two clock cycles after t_{RP} and t_{AOFD} have been satisfied the input clock frequency can be changed. A stable new clock frequency has to be provided, before CKE can be changed to a "high" logic level again. After t_{XP} has been satisfied a DLL RESET command via EMRS has to be issued. During the following DLL re-lock period of 200 clock cycles, ODT must remain off. After the DLL-re-lock period the DRAM is ready to operate with the new clock frequency.

Clock Frequency Change in Precharge Power Down Mode
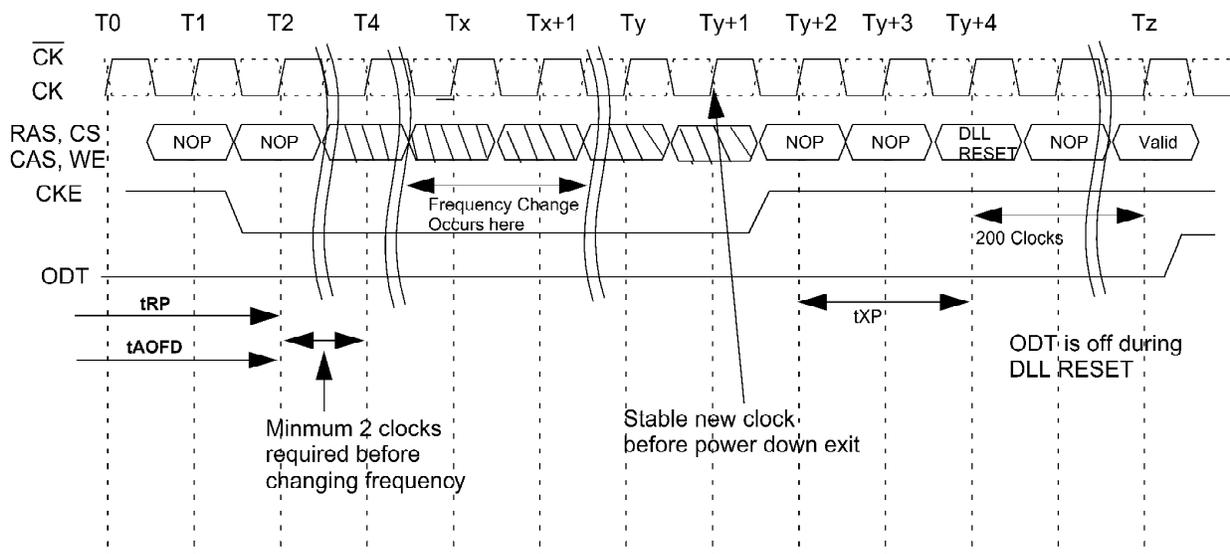

Asynchronous CKE Low Event

DRAM requires CKE to be maintained "high" for all valid operations as defined in this data sheet. If CKE asynchronously drops "low" during any valid operation DRAM is not guaranteed to preserve the contents of the memory array. If this event occurs, the memory controller must satisfy a time delay (t_{delay}) before turning off the clocks. Stable clocks must exist at the input of DRAM before CKE is raised "high" again. The DRAM must be fully re-initialized as described the initialization sequence starting with step 4.

The DRAM is ready for normal operation after the initialization sequence. The minimum time clocks need to be ON after CKE asynchronously drops low (the t_{delay} timing parameter) is equal to $t_{IS} + t_{CK} + t_{IH}$.

Asynchronous CLK Low Event
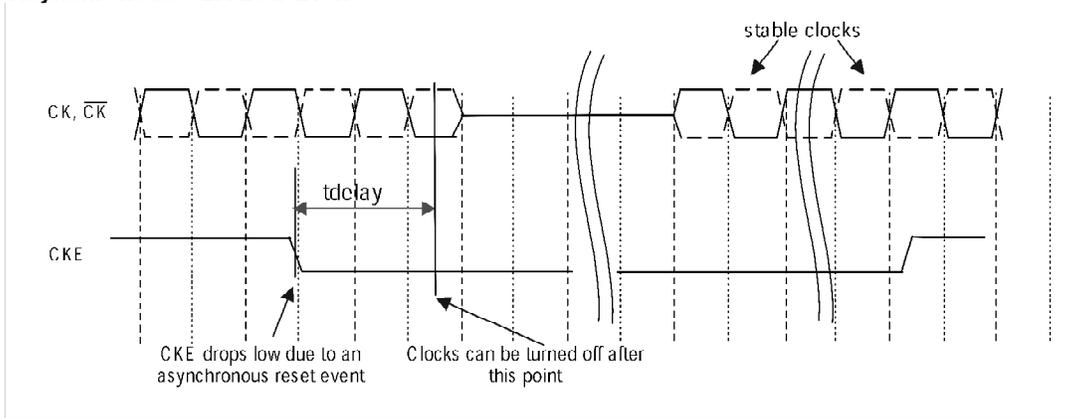

Command Truth Table

Function	CKE		$\overline{CS}$	$\overline{RAS}$	$\overline{CAS}$	$\overline{WE}$	BA0 - BAx[9]	Axx[9] – A11	A10	A9-A0	Notes
	Previous Cycle	Current Cycle									
(Extended) Mode Register Set	H	H	L	L	L	L	BA	OP Code			1,2
Refresh (REF)	H	H	L	L	L	H	X	X	X	X	1

			L	H	H	H					
Power Down Exit	L	H	H	X	X	X	X	X	X	X	1,4
			L	H	H	H					

NOTE 1 All DDR2 SDRAM commands are defined by states of $\overline{CS}$, $\overline{RAS}$, $\overline{CAS}$, $\overline{WE}$ and CKE at the rising edge of the clock

NOTE 2 Bank addresses BA0, BA1 (BA) determine which bank is to be operated upon. For (E)MRS BA selects an (Extended) Mode Register.

NOTE 3 Burst reads or writes at BL=4 cannot be terminated or interrupted. See sections "Reads interrupted by a Read" and "Writes interrupted by a Write" in section 2.6 for details.

NOTE 4 The Power Down Mode does not perform any refresh operations. The duration of Power Down is therefore limited by the refresh requirements outlined in section 2.9.

NOTE 5 The state of ODT does not affect the states described in this table. The ODT function is not available during Self Refresh. See section 2.4.4.

NOTE 6 "X" means "H or L (but a defined logic level)"

NOTE 7 Self refresh exit is asynchronous.

NOTE 8 V_{REF} must be maintained during Self Refresh operation.

NOTE 9 BAx and Axx refers to the MSBs of bank addresses and addresses, respectively, per device density.

Clock enable (CKE) truth table for synchronous transitions

Current State[2]	CKE		Command (N)[3] $\overline{RAS}, \overline{CAS}, \overline{WE}, \overline{CS}$	Action (N)[3]	Notes
	Previous Cycle[1] (N-1)	Current Cycle[1] (N-1)			
Power Down	L	L	X	Maintain Power-Down	11,13,14
	L	H	DESELECT or NOP	Power Down Exit	4,8,11,13
Self Refresh	L	L	X	Maintain Self Refresh	11,14,15
	L	H	DESELECT or NOP	Self Refresh Exit	4,5,9,15
Bank(s) Active	H	L	DESELECT or NOP	Active Power Down Entry	4,8,10,11,13
All Banks Idle	H	L	DESELECT or NOP	Precharge Power Down Entry	4,8,10,11,13
	H	L	REFRESH	Self Refresh Entry	6,9,11,13
	H	H	Refer to the Command Truth Table		7

NOTE 1   CKE (N) is the logic state of CKE at clock edge N; CKE (N–1) was the state of CKE at the previous clock edge.
NOTE 2   Current state is the state of the DDR2 SDRAM immediately prior to clock edge N.
NOTE 3   COMMAND (N) is the command registered at clock edge N, and ACTION (N) is a result of COMMAND (N).
NOTE 4   All states and sequences not shown are illegal or reserved unless explicitly described elsewhere in this document.
NOTE 5   On Self Refresh Exit DESELECT or NOP commands must be issued on every clock edge occurring during the t_{XSNR} period. Read commands may be issued only after t_{XSRD} (200 clocks) is satisfied.
NOTE 6   Self Refresh mode can only be entered from the All Banks Idle state.
NOTE 7   Must be a legal command as defined in the Command Truth Table.
NOTE 8   Valid commands for Power Down Entry and Exit are NOP and DESELECT only.
NOTE 9   Valid commands for Self Refresh Exit are NOP and DESELECT only.
NOTE 10 Power Down and Self Refresh can not be entered while Read or Write operations, (Extended) Mode Register Set operations or Precharge operations are in progress. See section Power-down and Self refresh operation for a detailed list of restrictions.
NOTE 11 $t_{CKE(min)}$ of 3 clocks means CKE must be registered on three consecutive positive clock edges. CKE must remain at the valid input level the entire time it takes to achieve the 3 clocks of registration. Thus, after any CKE transition, CKE may not transition from its valid level during the time period of $tIS + 2 \times t_{CK} + t_{IH}$.
NOTE 12 The state of ODT does not affect the states described in this table. The ODT function is not available during Self Refresh.
NOTE 13 The Power Down does not perform any refresh operations. The duration of Power Down Mode is therefore limited by the refresh requirements outlined in Refresh command section.
NOTE 14 "X" means "don't care (including floating around V_{REF})" in Self Refresh and Power Down. However ODT must be driven HIGH or LOW in Power Down if the ODT function is enabled (Bit A2 or A6 set to "1" in EMR(1)).
NOTE 15 V_{REF} must be maintained during Self Refresh operation.

DM truth table

Name (Functional)	DM	DQs	Note
Write Enable	L	Valid	1
Write inhibit	H	X	1
Note 1 Used to mask write data, provided coincident with corresponding data			

Operating Temperature Condition

Symbol	Parameter	Rating		Unit	Notes
		Min	Max		
Tcase	Case operating temperature for commercial temperature product	0	95	°C	1,2,3
Tcase	Case operating temperature for industrial temperature product	-40	95	°C	1,2,3
Tcase	Case operating temperature for high-temperature product	-40	105	°C	1,2,3

NOTE 1 Case operating temperature (Tcase) is the case surface temperature on the center/top side of the DRAM.

NOTE 2 During operation, the DRAM case temperature typically becomes higher than the ambient temperature. Tcase must be kept below the specified levels at all times.

NOTE 3 The Auto-Refresh command interval can be kept at the normal value t_{REFI}=7.8µs with Tcase ≤ 85°C. For operation between 85°C and 95°C, Refresh commands must be doubled in frequency, reducing the refresh interval t_{REFI} to 3.9µs is required. For operation above 95°C, 4 times Refresh rate is required, reducing the refresh interval t_{REFI} to 1.95µs. If the Self-Refresh operation is untilized at above 85°C Tcase, it is mandatory to use higher temperature self-refresh entry via the control of EMR(2) A7 = 1 with Extended Temperature Range capability. When the High Temperature Self-Refresh is enabled, there is an increase of IDD6 by approximately 50%.

Absolute maximum DC ratings

Symbol	Parameter	Rating	Units	Notes
V_{DD}	Voltage on V_{DD} pin relative to V_{SS}	-1.0 ~ 2.3	V	1,3
V_{DDQ}	Voltage on V_{DDQ} pin relative to V_{SS}	-0.5 ~ 2.3	V	1,3
V_{DDL}	Voltage on V_{DDL} pin relative to V_{SS}	-0.5 ~ 2.3	V	1,3
V_{IN}, V_{OUT}	Voltage on any pin relative to V_{SS}	-0.5 ~2.3	V	1
T_{STG}	Storage Temperature	-55 to +150	°C	1,2

NOTE 1 Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability

NOTE 2 Storage Temperature is the case surface temperature on the center/top side of the DRAM. Recommended storage temperature is not exceeding 105°C. Do not store at 150°C for more than 1000 hours. For the measurement conditions, please refer to JESD51-2 standard.

NOTE 3 When V_{DD} and V_{DDQ} and V_{DDL} are less than 500 mV, V_{REF} may be equal to or less than 300 mV. V_{DD} and V_{DDQ} must be within 300mV of each other at all times; and V_{REF} must not be greater than $0.6XV_{DDQ}$.

AC & DC operating conditions

Operation or timing that is not specified is illegal, and after such an event, in order to guarantee proper operation, the DRAM must be powered down and then restarted through the speechified initialization sequence before normal operation can continue.

Recommended DC operating conditions (SSTL_18)

Symbol	Parameter	Rating			Units	Notes
		Min.	Typ.	Max.		
V_{DD}	Supply Voltage	1.7	1.8	1.9	V	1, 5
V_{DDL}	Supply Voltage for DLL	1.7	1.8	1.9	V	5
V_{DDQ}	Supply Voltage for Output	1.7	1.8	1.9	V	1,5
V_{REF}	Input Reference Voltage	$0.49 \times V_{DDQ}$	$0.50 \times V_{DDQ}$	$0.51 \times V_{DDQ}$	mV	2,3
V_{TT}	Termination Voltage	$V_{REF} - 0.04$	V_{REF}	$V_{REF} + 0.04$	V	4

NOTE 1 There is no specific device V_{DD} supply voltage requirement for SSTL_18 compliance. However under all conditions V_{DDQ} must be less than or equal to V_{DD}.
NOTE 2 The value of V_{REF} may be selected by the user to provide optimum noise margin in the system. Typically the value of V_{REF} is expected to be about $0.5 \times V_{DDQ}$ of the transmitting device and V_{REF} is expected to track variations in V_{DDQ}.
NOTE 3 Peak to peak ac noise on V_{REF} may not exceed +/-2 % V_{REF}(dc).
NOTE 4 V_{TT} of transmitting device must track V_{REF} of receiving device.
NOTE 5 V_{DDQ} tracks with V_{DD}, V_{DDL} tracks with V_{DD}. AC parameters are measured with V_{DD}, V_{DDQ} and V_{DDL} tied together.

DC & AC Logic Input Levels

DDR2 SDRAM pin timing are specified for either single ended or differential mode depending on the setting of the EMRS "Enable $\overline{DQS}$" mode bit; timing advantages of differential mode are realized in system design. The method by which the DDR2 SDRAM pin timing are measured is mode dependent. In single ended mode, timing relationships are measured relative to the rising or falling edges of DQS crossing at V_{REF}. In differential mode, these timing relationships are measured relative to the crosspoint of DQS and its complement, $\overline{DQS}$. This distinction in timing methods is guaranteed by design and characterization. In single ended mode, the $\overline{DQS}$ (and $\overline{RDQS}$) signals are internally disabled and don't care.

Input DC logic level

Symbol	Parameter	Min.	Max.	Units	Notes
$V_{IH}(DC)$	DC input logic HIGH	$V_{REF} + 0.125$	$V_{DDQ} + 0.3$	V	
$V_{IL}(DC)$	DC input logic LOW	$- 0.3$	$V_{REF} - 0.125$	V	

Input AC logic level

Symbol	Parameter	DDR2-667,800,1066		Unit	Notes
		Min.	Max.		
$V_{IH}(AC)$	AC input logic HIGH	$V_{REF} + 0.200$	$V_{DDQ}+Vpeak$	V	
$V_{IL}(AC)$	AC input logic LOW	$V_{SSQ}-Vpeak$	$V_{REF}-0.200$	V	

AC input test conditions

Symbol	Condition	Value	Units	Notes
V_{REF}	Input reference voltage	$0.5 \times V_{DDQ}$	V	1
$V_{SWING(MAX)}$	Input signal maximum peak to peak swing	1.0	V	1
SLEW	Input signal minimum slew rate	1.0	V/ns	2, 3

NOTE 1 Input waveform timing is referenced to the input signal crossing through the $V_{IH/IL}(AC)$ level applied to the device under test.

NOTE 2 The input signal minimum slew rate is to be maintained over the range from V_{REF} to $V_{IH}(AC)$ min for rising edges and the range from V_{REF} to $V_{IL}(AC)$ max for falling edges as shown in the below figure.

NOTE 3 AC timings are referenced with input waveforms switching from $V_{IL}(AC)$ to $V_{IH}(AC)$ on the positive transitions and $V_{IH}(AC)$ to $V_{IL}(AC)$ on the negative transitions.

$$\text{Falling Slew} = \frac{V_{IH(dc)} \text{ min} - V_{IL(ac)} \text{ max}}{\text{delta TF}}$$

$$\text{Rising Slew} = \frac{V_{IH(ac)} \text{ min} - V_{IL(dc)} \text{ max}}{\text{delta TR}}$$
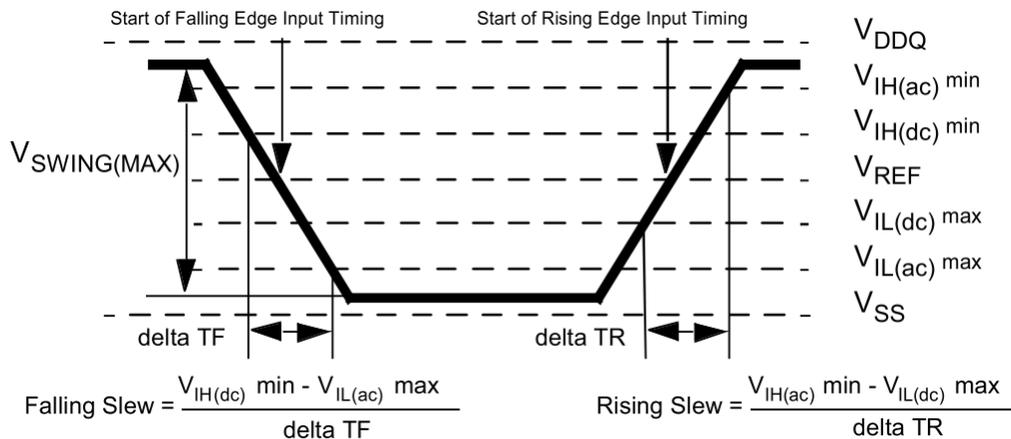

AC & DC operating conditions (cont'd)

Differential input AC logic level

Symbol	Parameter	DDR2-667,800		DDR2-1066		Unit	Notes
		Min	Max	Min	Max		
$V_{ID}(AC)$	AC differential input voltage	0.5	V_{DDQ}	0.5	V_{DDQ}	V	1
$V_{IX}(AC)$	AC differential crosspoint voltage	$0.5xV_{DDQ}$ -0.175	$0.5xV_{DDQ}$ +0.175	$0.5xV_{DDQ}$ -0.175	$0.5xV_{DDQ}$ +0.175	V	2

NOTE 1 $V_{ID}(AC)$ specifies the input differential voltage | V_{TR} -V_{CP} | required for switching, where V_{TR} is the true input signal (such as CK, DQS, RDQS) and V_{CP} is the complementary input signal (such as $\overline{CK}$, $\overline{DQS}$, $\overline{RDQS}$). The minimum value is equal to $V_{IH}(AC)$ - $V_{IL}(AC)$.

NOTE 2 The typical value of $V_{IX}(AC)$ is expected to be about 0.5 x V_{DDQ} of the transmitting device and $V_{IX}(AC)$ is expected to track variations in V_{DDQ}. $V_{IX}(AC)$ indicates the voltage at which differential input signals must cross.

Differential signal levels

Differential AC output parameters

Symbol	Parameter	Min	Max	Unit	Notes
$V_{OX}(AC)$	AC differential crosspoint voltage	$0.5 \times V_{DDQ} - 0.125$	$0.5 \times V_{DDQ} + 0.125$	V	1

NOTE 1 The typical value of $V_{OX}(AC)$ is expected to be about 0.5 x V_{DDQ} of the transmitting device and $V_{OX}(AC)$ is expected to track variations in V_{DDQ}. $V_{OX}(AC)$ indicates the voltage at which differential output signals must cross.

Overshoot/undershoot specification

AC overshoot/undershoot specification for address and control pins:

A0-A13, BA0-BA2, $\overline{CS}$, $\overline{RAS}$, $\overline{CAS}$, $\overline{WE}$, CKE, ODT

Parameter	DDR2-667	DDR2-800	DDR2-1066	Unit
Maximum peak amplitude allowed for overshoot area	0.5	0.5	0.5	V
Maximum peak amplitude allowed for undershoot area	0.5	0.5	0.5	V
Maximum overshoot area above V_{DDQ}	0.8	0.66	0.5	V-ns
Maximum undershoot area below V_{SSQ}	0.8	0.66	0.5	V-ns

AC & DC operating conditions (cont'd)

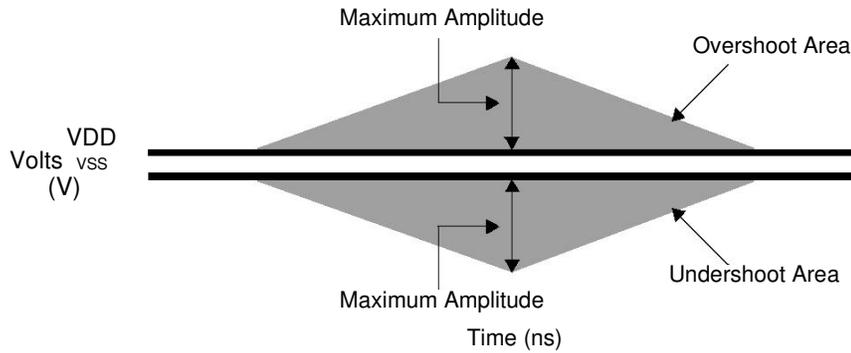

AC overshoot and undershoot definition for address and control pins

AC overshoot/undershoot specification for clock, data, strobe, and mask pins:

DQ, RDQS, $\overline{RDQS}$, DM, CK, $\overline{CK}$

Parameter	DDR2-667	DDR2-800	DDR2-1066	Unit
Maximum peak amplitude allowed for overshoot area	0.5	0.5	0.5	V
Maximum peak amplitude allowed for undershoot area	0.5	0.5	0.5	V
Maximum overshoot area above V_{DDQ}	0.23	0.23	0.19	V-ns
Maximum undershoot area below V_{SSQ}	0.23	0.23	0.19	V-ns
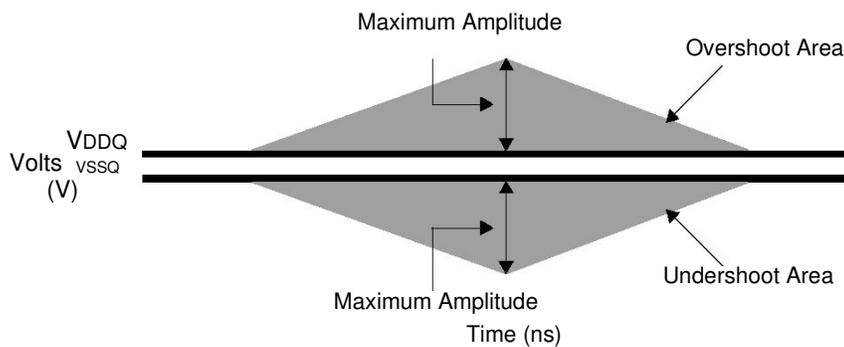

AC overshoot and undershoot definition for clock, data, strobe, and mask pins

Power and ground clamps are required on the following input only pins:

a) BA0-BAx   e) $\overline{WE}$

b) A0-A13   f) $\overline{CS}$

c) $\overline{RAS}$ g) ODT

d) $\overline{CAS}$ h) CKE

AC & DC operating conditions (cont'd)

V-I characteristics for input-only pins with clamps

Output buffer characteristics

Output AC test conditions

Symbol	Parameter	SSTL_18	Units	Notes
V_{OTR}	Output Timing Measurement Reference Level	0.5 x V_{DDQ}	V	1

NOTE 1 The VDDQ of the device under test is referenced.

Output DC current drive

Symbol	Parameter	SSTI_18	Units	Notes
I_{OH}(DC)	Output Minimum Source DC Current	- 13.4	mA	1, 3, 4
I_{OL}(DC)	Output Minimum Sink DC Current	13.4	mA	2, 3, 4

NOTE 1 V_{DDQ} = 1.7 V; V_{OUT} = 1420 mV. (V_{OUT} - V_{DDQ}) / I_{OH} must be less than 21 for values of V_{OUT} between V_{DDQ} and V_{DDQ} - 280 mV.
NOTE 2 V_{DDQ} = 1.7V; V_{OUT} = 280 mV. V_{OUT} / I_{OL} must be less than 21 for values of V_{OUT} between 0 V and 280mV.
NOTE 3   The DC value of V_{REF} applied to the receiving device is set to $V_{TT.}$
NOTE 4   The values of I_{OH}(DC) and I_{OL}(DC) are based on the conditions given in Notes 1 and 2. They are used to test device drive current capability to ensure V_{IH} min plus a noise margin and V_{IL} max minus a noise margin are delivered to an SSTL_18 receiver. The actual current values are derived by shifting the desired driver operating point (see Section 3.3 of JESD8-15A) along a 21 load line to define a convenient driver current for measurement.

Figure 2. DDR2 Default Pullup Characteristics for Full Strength Driver
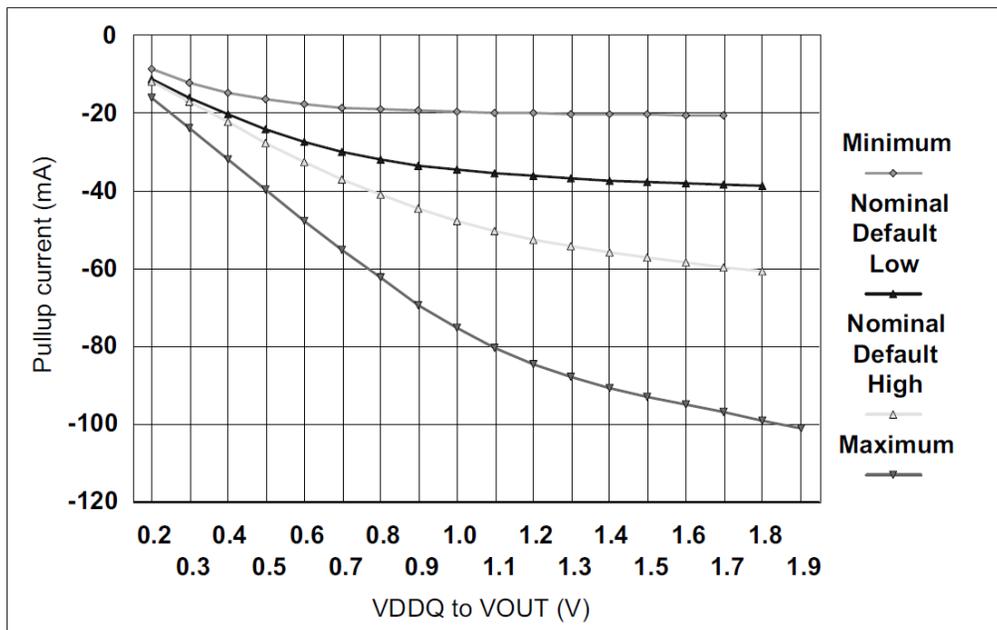

DDR2 SDRAM Calibrated Output Driver V-I Characteristics

Tables 3 and 4 show the data in tabular format suitable for input into simulation tools. The nominal points represent a device at exactly 18 ohms. The nominal low and nominal high values represent the range that can be achieved with a maximum 1.5 ohm step size with no calibration error at the exact nominal conditions only (i.e. perfect calibration procedure, 1.5 ohm maximum step size guaranteed by specification). Real system calibration error needs to be added to these values.

It must be understood that these V-I curves as represented here or in supplier IBIS models need to be adjusted to a wider range as a result of any system calibration error. Since this is a system specific phenomenon, it cannot be quantified here. The values in the calibrated tables represent just the DRAM portion of uncertainty while looking at one DQ only. If the calibration procedure is used, it is possible to cause the device to operate outside the bounds of the default device characteristics tables and figures.

In such a situation, the timing parameters in the specification cannot be guaranteed. It is solely up to the system application to ensure that the device is calibrated between the minimum and maximum default values at all times. If this can't be guaranteed by the system calibration procedure, re-calibration policy, and uncertainty with DQ to DQ variation, then it is recommended that only the default values be used.

The nominal maximum and minimum values represent the change in impedance from nominal low and high as a result of voltage and temperature change from the nominal condition to the maximum and minimum conditions. If calibrated at an extreme condition, the amount of variation could be as much as from the nominal minimum to the nominal maximum or vice versa. The driver characteristics evaluation conditions are:

Nominal 25°C (Tcase), V_{DDQ} = 1.8 V, typical process

Nominal Low and Nominal High 25°C (Tcase), V_{DDQ} = 1.8 V, any process

Nominal Minimum 85°C (Tcase), V_{DDQ} = 1.7 V, any process

Nominal Maximum 0°C (Tcase), V_{DDQ} = 1.9 V, any process

Table 3. Full Strength Calibrated Pulldown Driver Characteristics

Voltage (V)	Calibrated Pulldown Current (mA)				
	Nominal Minimum (21ohm)	Nominal Low (18.75ohm)	Nominal (18ohm)	Nominal High (17.25ohm)	Nominal Maximum (15ohm)
0.2	9.5	10.7	11.5	11.8	13.3
0.3	14.3	16.0	16.6	17.4	20.0
0.4	18.7	21.0	21.6	23.0	27.0

Table 4. Full Strength Calibrated Pullup Driver Characteristics

Voltage (V)	Calibrated Pulldown Current (mA)				
	Nominal Minimum (21ohm)	Nominal Low (18.75ohm)	Nominal (18ohm)	Nominal High (17.25ohm)	Nominal Maximum (15ohm)
0.2	-9.5	-10.7	-11.4	-11.8	-13.3
0.3	-14.3	-16.0	-16.5	-17.4	-20.0

IDD specification parameters and test conditions

(IDD values are for full operating range of Voltage and Temperature, Notes 1-6)

NOTE 1   IDD specifications are tested after device is properly initialized.
NOTE 2   Input slew rate is specified by AC Parameter Test Condition
NOTE 3   IDD parameters are specified with ODT disabled
NOTE 4   Data bus consists of DQ, DM, DQS, $\overline{DQS}$, RDQS and $\overline{RDQS}$. IDD values must be met with all combinations of EMRS bits 10 and 11
NOTE 5   For DDR2-667/800 testing, t_{CK} in the Conditions should be interpreted as t_{CK}(avg)
NOTE 6   Definitions for IDD

LOW	=	$Vin \leq V_{ILAC}$ (max)
HIGH	=	$Vin \geq V_{IHAC}$ (min)
STABLE	=	inputs stable at a HIGH or LOW level
FLOATING	=	inputs at $V_{REF} = V_{DDQ}/2$
SWITCHING	=	inputs changing between HIGH and LOW every other clock cycle (once per two clocks) for address and control signals, and inputs changing between HIGH and LOW every other data transfer (once per clock) for DQ signals not including masks or strobes

IDD testing parameters

For purposes of IDD testing, the parameters in the IDD testing parameters table are to be untilized.

IDD testing parameters

Speed	DDR2-1066	DDR2-800	DDR2-667	Unit
Bin(CL-Trcd-tRP)	7-7-7	5-5-5	5-5-5	
CL(IDD)	7	5	5	t_{CK}

t_{RAS}min(IDD)	45	45	45	ns
t_{RAS}max(IDD)	70000	70000	70000	ns
t_{RP}(IDD)	13.125	12.5	15	ns
t_{RCF}(IDD)-1Gb	127.5	127.5	127.5	ns

AC & DC operating conditions(cont'd)

Detailed IDD7

The detailed timings are shown below for IDD7. Changes will be required if timing parameter changes are made to the specification. Legend: A = Active; RA = Read with Autoprecharge; D = Deselect

IDD7: Operating Current: All Bank Interleave Read operation

All banks are being interleaved at minimum t_{RC}(IDD) without violating t_{RRD}(IDD) and t_{FAW}(IDD) using a burst length of 4. Control and address bus inputs are STABLE during DESELECTs. IOUT = 0 mA

Notes for Electrical Characteristics & AC Timing

1. Input slew rate is 1 V/ns and AC timings are guaranteed for linear signal transitions. For other slew rates see the derating tables on the next pages.

2. The CK / $\overline{CK}$ input reference level (for timing reference to CK / $\overline{CK}$) is the point at which CK and $\overline{CK}$ cross: the DQS / $\overline{DQS}$ input reference level is the crosspoint when in differential strobe mode; the input reference level for signals other than CK/$\overline{CK}$, or DQS / $\overline{DQS}$ is V_{REF}.

3. Inputs are not recognized as valid until V_{REF} stabilizes. During the period before V_{REF} stabilizes, CKE = 0.2 x V_{DDQ} is recognized as LOW.

4. The output timing reference voltage level is V_{TT}.

5. Min (t_{CL}, t_{CH}) refers to the smaller of the actual clock low time and the actual clock high time as provided to the device (i.e. this value can be greater than the minimum specification limits for t_{CL} and t_{CH}.

6. For input frequency change during DRAM operation.

7. t_{HZ} and t_{LZ} transitions occur in the same access time windows as valid data transitions. These parameters are not referred to a specific voltage level, but specify when the device is no longer driving (HZ), or begins driving (LZ).

8. These parameters guarantee device timing, but they are not necessarily tested on each device.

9. The specific requirement is that DQS and $\overline{DQS}$ be valid (HIGH, LOW, or some point on a valid transition) on or before this CK edge. A valid transition is defined as monotonic and meeting the input slew rate specifications of the device. When no writes were previously in progress on the bus, DQS will be transitioning from Hi-Z to logic LOW. If a previous write was in progress, DQS could be HIGH, LOW, or transitioning from HIGH to LOW at this time, depending on tDQSS. When programmed in differential strobe mode, DQS is always the logic complement of DQS except when both are in high-Z.

10. The maximum limit for this parameter is not a device limit. The device operate with a greater value for this parameter, but system performance (bus turnaround) degrades accordingly.

11. A maximum of eight Auto-Refresh commands can be posted to any given DDR2 SDRAM device. (Note : t_{RFC} depends on DRAM density)

12. For each of the terms, if not already an integer, round to the next highest integer. t_{CK} refers to the application clock period. WR refers to the WR parameter stored in the MRS.

13. t_{WTR} is at least two clocks independent of operation frequency.

14. User can choose two different active power-down modes for additional power saving via MRS address bit A12. In "standard active power-down mode" (MRS, A12 = "0") a fast power-down exit timing t_{XARD} can be used. In "low active power-down mode" (MRS, A12 ="1") a slow power-down exit timing t_{XARDS} has to be satisfied.

15. Timings are guaranteed with command / address input slew rate of 1.0 V/ns.

16. Timings are guaranteed with data / mask input slew rate of 1.0 V/ns.

17. Timings are guaranteed with CK /$\overline{CK}$ differential slew rate 2.0 V/ns, and DQS/$\overline{DQS}$ (and RDQS/$\overline{RDQS}$) differential slew rate 2.0 V/ns in differential strobe mode.

18. If refresh timing or t_{DS} / t_{DH} is violated, data corruption may occur and the data must be re-written with valid data before a valid READ can be executed.

19. In all circumstances, t_{XSNR} can be satisfied using t_{XSNR} = t_{RFC} + 10 ns.

20. The t_{RCD} timing parameter is valid for both activate command to read or write command with and without Auto-Precharge. Therefore a separate parameter t_{RAP} for activate command to read or write command with Auto-Precharge is not necessary anymore.

21. t_{RAS}(max) is calculated from the maximum amount of time a DDR2 device can operate without a Refresh command which is equal to 9 * t_{REFI}.

Reference Loads, Slew Rates and Slew Rate Derating

Reference Load for Timing Measurements

The figure represents the timing reference load used in defining the relevant timing parameters of the device. It is not intended to either a precise representation of the typical system environment nor a depiction of the actual load presented by a production tester. System designers will use IBIS or other simulation tools to correlate the timing reference load to a system environment. This load circuit is also used for output slew rate measurements.

Timing Reference Points
Note: The output timing reference voltage level for single ended signals is the crosspoint with VTT.
The output timing reference voltage level for differential signals is the crosspoint of the
true (e.g. DQS) and the complement (e.g. $\overline{DQS}$) signal.
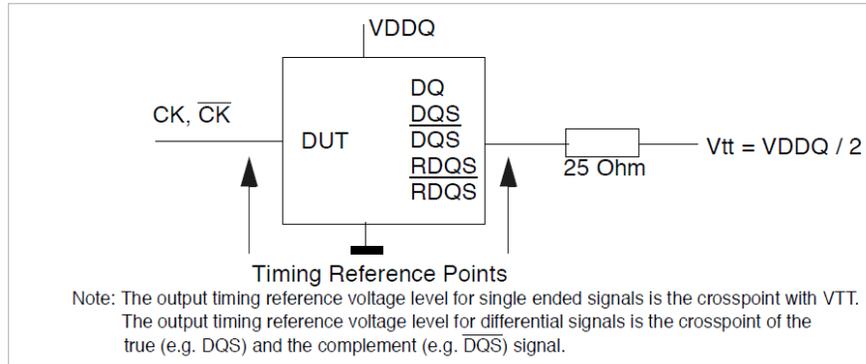

Slew Rate Measurements

Output Slew Rate

Output slew rate is characterized under the test conditions as shown in the figure below
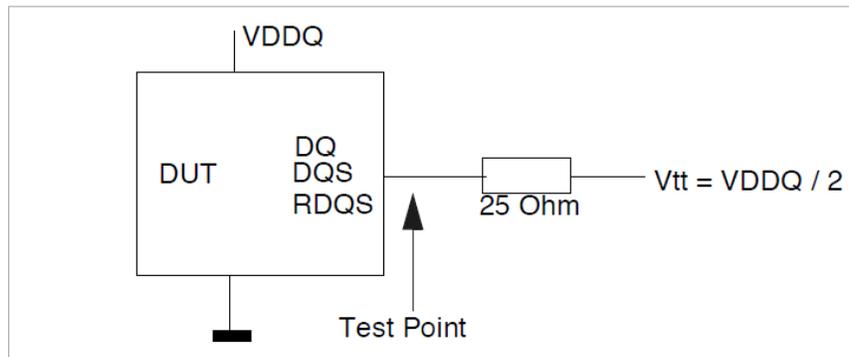

Output slew rate for falling and rising edges is measured between V_{TT} - 250 mV and V_{TT} + 250 mV for single ended signals. For differential signals (e.g. DQS - $\overline{DQS}$) output slew rate is measured between DQS - $\overline{DQS}$ = - 500 mV and DQS - $\overline{DQS}$ = + 500 mV. Output slew rate is guaranteed by design, but is not necessarily tested on each device.

Input Slew Rate

Input slew for single ended signals is measured from dc-level to ac-level from V_{REF} to V_{IH}(AC), min for rising and from V_{REF} to V_{IL}(AC), min or falling edges.
For differential signals (e.g. CK - $\overline{CK}$) slew rate for rising edges is measured from CK - $\overline{CK}$ = -250 mV to CK - $\overline{CK}$ = +500 mV (250 mV to -500 mV for falling edges). Test conditions are the same as for timing measurements.
